Preface to the Second Edition

Archaeology – the study of human cultures through the analysis and interpretation of artifacts and material remains – continues to captivate and engage people on a local and global level. The significance of international heritage sites such as the pyramids – both Egyptian and Mayan – the Lascaux caves, the Taj Mahal, and Petra all provide insights into our ancestors and their actions and motivations. However, there is much more to archaeology than famous sites. When archaeologists are asked to elaborate about their job, they will touch on archaeological theory, chemistry, geology, history, classical studies, museum studies, ethical practice, and survey methods, along with the analysis and interpretation of their sites. Archaeology is a much broader subject than its public image and branches out to many other fields in the humanities and in the social and hard sciences.

The *Encyclopedia of Global Archaeology* provides a comprehensive and systematic coverage of archaeology that is unprecedented. It encompasses the breadth of the subject area along with those aspects that are tapped by other disciplines. In addition, it encompasses all time periods and regions of the world and all stages of human development. The entries range from succinct summaries of specific sites and the scientific aspects of archaeological enquiry, to detailed discussions of archaeological concepts, theories, and practice, the social and political dimensions of archaeology and archaeological ethics. The different forms of archaeology are explored, along with their respective techniques as well as the challenges, concerns, and issues that face archaeologists today.

This 18 volume *Encyclopedia of Global Archaeology* is available in both print and eReference versions. The print version of the second edition has 1964 contributions from 1630 authors and over 12729 cross-references. At the time of publication, many more entries have been commissioned for the eReference version. Through constant updating, the eReference version of the *Encyclopedia of Global Archaeology* will continue to access the best scholarship from around the world. Our aim is to ensure that this reference work will be as useful in 20 years as it is in two years.

An Encyclopedia for a Global World

The *Encyclopedia of Global Archaeology* was designed to be a definitive reference work for archaeologists, cultural heritage managers, and the general public. Its major aim is to disseminate global expertise in archaeology.

We have achieved this through four innovations: an unparalleled level of contributions from archaeologists who do not normally publish in English, the conscious inclusion of multiple perspectives on key topics, biographies of major archaeological figures from throughout the world, and the combination of print and continuously updated eReference publication.

The first major challenge for this encyclopedia was to access the best scholarship in the world. There was a fundamental problem, however: archaeological experts around the globe do not always write in English. For example, the problems of site conservation and preservation can be very different in different parts of the world – and the experts publish in their own languages. Some of the most advanced thinking on archaeological theory comes from South America, while the French and Spanish have the deepest knowledge of Upper Paleolithic rock art and the place to learn about large-scale urban excavations or historic reconstructions is Japan. The experts from these countries publish their research in their own language. While some also publish in English, many don't – and even scholars who speak English can be reluctant to publish in English, as they may not have the level of written competency to fully express the complexity of their ideas. Not all specialist knowledge is published in English.

The answer was to allow non-English-language speakers to contribute to the encyclopedia in their own language. This accessed a torrent of hitherto untapped expertise. Around 180 entries and more than 350,000 words in the *Encyclopedia of Global Archaeology* have been translated from French, Italian, Portuguese, Russian, German, and Spanish. In addition, many more entries were submitted by authors whose first language is Chinese, Japanese, or Turkish. Often, these entries involved significant editing, rewriting, and polishing in order to ensure academic standards and clear communication. This painstaking work was undertaken by me anthropologist Gary Jackson or by the editors of the relevant sections. The authors and translators often had to review several versions of the text, and did so without complaint. This cooperative and cosmopolitan approach has brought enormous strengths to the encyclopedia and produced something that is quite different to what has come before.

The second challenge was to maximize the value of the *Encyclopedia of Global Archaeology* as a teaching resource for schools, colleges, and universities. Some of the best learning is achieved through comparison and debate. Accordingly, we have included multiple and regional perspectives on key topics to facilitate comparisons, especially at a global level, and provided rich materials for classroom debates. The ethics of commercial archaeology, for example, has individual entries that provide perspectives from Australia, Brazil, Japan, Nigeria, Southern Africa, and the USA. While each entry provides an in-depth discussion of the issues that affect a particular region, taken together, these entries provide the materials required for students to undertake analyses of contrasts and comparisons at a global level.

The third challenge was to honor the work of archaeologists from across the world. The biographies, and occasional autobiographies, in the encyclopedia were commissioned by Section Editors or by myself as Editor on the basis of the contribution of particular archaeologists to specific disciplinary areas and also through recommendations from archaeologists in underrepresented countries. While we attempted to obtain some form of uniform global coverage in archaeological biographies, this was not possible as archaeology is at different stages of development in different parts of the world. The need to build archaeological capacity is greatest on the African continent. The small number of biographies of African archaeologists reflects the small number of archaeologists in the continent as a whole. While the vast majority of these archaeologists are located in South Africa, there are key nodes in countries such as Kenya and Nigeria. Sometimes these nodes are an outcome of capacity building that occurred as part of colonial processes, as with the life work of Charles Thurstan Shaw. Some biographies honor the work of archaeologists who spent their lives building capacity in a part of the world that is not their home country, as with the work of Betty Meggers in South America. All of the biographies provide insights into the life histories of archaeologists in various periods and in diverse parts of the world. Moreover, cultural attitudes are apparent in the profiles of biographies for each region. For example, while many Portuguese biographies are of mid-career archaeologists who are still alive, the majority of biographies of Japanese archaeologists are of people who shaped important aspects of the profession and have now passed away.

The final challenge was to harness the potential of an online environment not only to ensure global accessibility but also to enrich the encyclopedia's content. From the beginning, the *Encyclopedia of Global Archaeology* was conceived firstly as an online reference work, and then as a print reference. This interactive, online reference uses dynamic content to deepen discussions and to update material published in the print version, and to add information on new finds, or new ways of approaching the material. Hot links and extensive cross-references between keywords and related articles provide topics with greater depth and enable efficient searches in a user-friendly manner. The important innovation here is the continuous updating of entries and the ongoing addition of new entries to the eReference version. This will ensure that the encyclopedia maintains ongoing relevance.

So, what is different about the second edition of the *Encyclopedia of Global Archaeology*? Firstly, when we started the second edition, we knew it was built on a strong foundation. We gained confidence to experiment a little more as we came to appreciate that this flexible, international, interdisciplinary (sometimes postdisciplinary) approach to scholarship is successful. At the time of writing the encyclopedia has had nearly 400,000 downloads, according to Bookmetrics. Physical copies are in 348 WorldCat member libraries worldwide, and many more have access to the digital version. In 2019, the *Encyclopedia of Global Archaeology* was the third most cited and the fourth most downloaded of 804 books in Springer's 2014 Humanities, Law and Social Sciences collection. By early 2020, the first edition had been cited 635 times. We can be confident that people are using, and citing, this encyclopedia.

The first edition was well received. The highlight for me was a review essay by the editors of *Antiquity.* They stated that:

> The involvement of more than the usual English-language cohort of contributors definitely gives this encyclopedia a special character and strengthens its international credentials . . . it is easy to imagine recommending students to begin their research on almost any topic by consulting the entries in these volumes. As a starting point for research, the Encyclopedia—and especially its eReference version—would be a very welcome resource for any archaeology student. More broadly, as a snapshot of the discipline, it is unparalleled. (Chris Scarre and Robert Witcher, *Antiquity*, Vol. 89 (343), February, 2015)

The authors of chapters in this encyclopedia are distinguished senior and mid-career scholars, as well as early career researchers. Participation is by invitation only: each chapter was solicited from a scholar who is an expert in that particular field. Each chapter has been peer-reviewed by at least two referees. The chapters were rewritten taking into account the comments of referees. This enhances the quality of the work. Each chapter is a work of original scholarship. Even the review chapters include original scholarship in terms of the theoretical frameworks and interpretations that are taken to the material. With some 2,000 chapters the *Encyclopedia of Global Archaeology* encompasses a formidable body of original research.

For the second edition we consciously tried to fill gaps that exist in the first edition. At times, this has been difficult as we wanted to solicit the chapter from someone who is a specialist in that particular field of study. The glaring example for me is Hadrian's Wall. The first edition does not have a chapter on the archaeology of Hadrian's Wall. Neither does the print copy of the second edition – but the online version does. We needed to wait for Rob Collins of Newcastle University in the United Kingdom to fit writing the chapter on Hadrian's Wall into his schedule. So, rather than seeking this chapter from someone who is less expert on the subject matter, we waited. The success of this approach is apparent in the comments of one of the anonymous reviewers of this chapter:

> I have read through the submission on Hadrian's Wall and am very impressed. Rob is an established Wall expert and actively involved in both researching it, and teaching university students about it. As a result, the text is factually accurate, up-to-date with current thinking, and successfully distils a massive subject into a concise and original piece of text. I have never before written a review without any suggestions for improvements, but on this occasion I really don't think anything needs to be added (or taken away) or rethought. (Anonymous reviewer, 27 February 2020)

Hadrian's Wall is also the subject of an innovation of the second edition, the inclusion of experiential chapters in relation to major sites. Leslie Carlin has written an engaging, lyrical chapter, "Writing on the Wall," that significantly broadens our understanding of the experience of visiting Hadrian's Wall:

> The view is stunning. There is a wall, and there are the rolling green hills and heathered soil supporting – fertilizing – the wall. Nothing more, bar the stretching sky, blue and gray, over the narrow length of stone unspooling east and west . . . In a way, in the hold it has on the world's imagination, it circles the globe. The narrative of men from Rome and from its conquered lands, ranging from the eastern Mediterranean to northwest Africa, walking north and further north and building a wall for their emperor and homes and bathhouses and lives for themselves, is a small story about the bigger story of human migration. Those men left their graffiti and their genes behind. A rare African Y chromosome has been traced to a lineage in Leicester and may well have come from a soldier guarding Hadrian's Wall. (Carlin 2020, these volumes)

This expressive, experiential chapter by Leslie Carlin perfectly complements the deep archaeological knowledge of the chapter by Rob Collins, each adding depth to the other. I would be interested in developing this approach in future editions.

The second edition of the *Encyclopedia of Global Archaeology* is broader in concept than the original. It is informed by a definition of archaeology that I developed, partly through working on the encyclopedia, archaeology as "the study of human behaviour, past and present, through the analysis of material culture, both real and virtual, as situated within cultural landscapes" (Claire Smith, *Pyrenae*, Vol. 48 (1), April, 2017). In this edition of the encyclopedia, there is a greater emphasis on the virtual realm, evident in chapters such as Jordan Ralph and Tom Bowden's "Archaeology of internet memes," Dr. João Carlos Moreno de Sousa's "Internet use for archaeological education," and Paul Graves-Brown's "Archaeology of the internet." I imagine that more chapters in this vein will be published in the online editions of the encyclopedia.

I love the biographies, especially of those archaeologists from countries whose first language is not English. I have learnt a lot about the scholars who established archaeology in Japan, Argentina, Russia, India, and other parts of the world. I have learnt about their lives as well as their archaeological achievements. Many of us have exciting lives, even if we are not Indiana Jones, Lara Croft, or Nathan Drake. I was particularly taken with the biographies of Nancy Hatch Dupree and Louis Benjamin Dupree, written by the eminent scholar Charles C. Kolb. While traditional biographies of archaeologists tend to focus on the subject's archaeological career, we encourage authors to personalize their subjects. Professor Kolb delves into the backgrounds of the Duprees and really brings them to life. So, we learn that Nancy Hatch Dupree's first husband, Alan Wolfe, was assigned to Afghanistan in 1962 as a cultural attaché to the US Embassy but in reality he was the CIA station chief. This marriage ended when Nancy fell in love with Louis Dupree, in an unusual exchange of partners:

> Their extramarital love affair caused a scandal in Kabul, and by 1966 Nancy and Louis had divorced their respective spouses and married in February 1966 (Alan Wolfe and Ann Dupree also married each other). Nancy and Louis would stay in Afghanistan conducting research and writing until the Soviet invasion in 1978. (Kolb 2020, Nancy Hatch Dupree)

Given his association with Alan Wolfe, it is somehow not surprising that "Louis was arrested as a suspected spy by the pro-Soviet Afghan government in April 1978, cruelly interrogated, and ultimately expelled by the new Communist regime" (Kolb 2020, Louis B. Dupree). Regarding Louis Dupree's outstanding achievements in Afghan and Pakistani archaeology, readers are provided with the material to interpret these achievements in terms of his lifelong commitment to people in this region. We also learn that Louis Dupree was a US Army paratrooper in North Africa during the Second World War, and was awarded a Purple Heart and Bronze Star. In fact, his life seems quite like that of Indiana Jones to me:

> After being wounded during a jump, he went to the Philippines in the late 1944, parachuting behind Japanese lines to organize native guerrilla units – the

Hukbalahap – an experience that he later credited with having inspired his interest in ethnography . . .

> Following the Marxist coup d'etat in Afghanistan in April 1978, Louis Dupree was imprisoned and interrogated by Afghans and their Soviet KGB advisors before being released through the intervention of Afghan friends. (Kolb 2020, Louis B. Dupree)

The archaeological achievements of Nancy and Louis Dupree are presented within the wider context in which they lived:

> The Duprees had conceived and established a predecessor to the Afghanistan Centre at Kabul University (ACKU) in Peshawar. This activity was the Duprees' response to the looting or destruction of private, university, and public libraries in Kabul – much in the manner that the National Museum collections had been decimated ... By 1999 Nancy had amassed 7,739 titles written in Pashto, Dari, and several European languages. She returned to Kabul in 2005, smuggling in a unique collection of 35,000 documents in 300 plastic fertilizer sacks. Two years later, the Afghanistan Centre at Kabul University was physically established on the Kabul campus. (Kolb 2020, Nancy Hatch Dupree)

As with the Duprees, each biographical chapter in this encyclopedia allows the reader to obtain insights from other chapters. It is simple to find these links between people, and other subject matter, through the cross references. I enjoin you to read all the biographies – it seems to me that this is a shortcut to learning about world archaeology within the context of the time.

Welcome to the second edition of the *Encyclopedia of Global Archaeology.* I have read, and learnt from, every chapter. I hope that you, too, will enjoy and learn from the material you read in this encyclopedia. Finally, I return to the review in *Antiquity*:

> The city's panegyrists described it [Rome] as a cosmopolis, a place where the full diversity of the known world—its peoples, ideas, animals, plants and things of every kind—could be experienced in a single place. Such is the *Encyclopedia of Global Archaeology.* (Chris Scarre and Robert Witcher, *Antiquity*, Vol. 89 (343), February, 2015)

Preface to the First Edition

Archaeology – the study of human cultures through the analysis and interpretation of artifacts and material remains – continues to captivate and engage people on a local and global level. The significance of such international heritage sites such as the pyramids – both Egyptian and Mayan – the Lascaux caves, Stonehenge, and Petra all provide insights into our ancestors and their actions and motivations. However, there is much more to archaeology than famous sites. When archaeologists are asked to elaborate about their job, they will touch on archaeological theory, chemistry, geology, history, classical studies, museum studies, ethical practice, and survey methods, along with the analysis and interpretation of their sites. Archaeology is a much broader subject than its public image and branches out to many other fields in the social and hard sciences.

The *Encyclopedia of Global Archaeology* provides a comprehensive and systematic coverage of archaeology that is unprecedented. It encompasses the breadth of the subject area along with those aspects that are tapped by other disciplines. In addition, it encompasses all time periods and regions of the world and all stages of human development. The entries range from succinct summaries of specific sites and the scientific aspects of archaeological enquiry, to detailed discussions of archaeological concepts, theories, and practice, the social and political dimensions of archaeology and archaeological ethics. The different forms of archaeology are explored, along with the techniques used for each and the challenges, concerns, and issues that face archaeologists today.

This 11 volume *Encyclopedia of Global Archaeology* is available in both print and eReference versions. The print version has 1,625 contributions from 1,356 authors and over 11,634 cross-references. At the time of publication, another 200 entries have been commissioned for the eReference version. Through constant updating, the eReference version of the *Encyclopedia of Global Archaeology* will continue to access the best scholarship from around the world. Our aim is to ensure that this reference work will be as useful in twenty years as it is in two years.

An Encyclopedia for a Global World

The *Encyclopedia of Global Archaeology* was designed to be a definitive reference work for archaeologists, cultural heritage managers, and the general public. Its major aim is to disseminate global expertise in archaeology. We

have achieved this through four innovations: an unparalleled level of contributions from archaeologists who do not normally publish in English, the conscious inclusion of multiple perspectives on key topics, biographies of major archaeological figures from throughout the world, and the combination of print and continuously up-dated eReference publication.

The first major challenge for this encyclopedia was to access the best scholarship in the world. However, there was a fundamental problem – archaeological experts around the globe do not always write in English. The best scholars from throughout the world write in a variety of languages. For example, the problems of site conservation and preservation can be very different in different parts of the world – and the experts publish in their own languages. Moreover, not all specialist knowledge is published in English. Some of the most advanced thinking on archaeological theory comes from South America, while the French and Spanish have the deepest knowledge of Upper Paleolithic rock art and the place to learn about largescale urban excavations or historic reconstructions is Japan. The experts from these countries publish their research in their own language. While some also publish in English, many don't – and even scholars who speak English can be reluctant to publish in English, as they may not have the level of written competency to fully express the complexity of their ideas.

The answer was to allow non-English-language speakers to contribute to the encyclopedia in their own language. This accessed a torrent of hitherto untapped expertise. Around 140 entries and more than 300,000 words in the *Encyclopedia of Global Archaeology* have been translated from French, Italian, Portuguese, Russian and Spanish. In addition, many more entries were submitted by authors whose first language is Chinese, German, Japanese, or Turkish. Often, these entries involved significant editing, re-writing, and polishing in order to ensure academic standards and clear communication. This painstaking work was undertaken by the editors of the relevant sections and by myself. The authors and translators often had to review several versions of the text, and they did this without complaint. This cooperative and cosmopolitan approach has brought enormous strengths to the encyclopedia and produced something that is quite different to what has come before.

The second challenge was to maximize the value of the *Encyclopedia of Global Archaeology* as a teaching resource for schools, colleges, and universities. Some of the best learning is achieved through comparison and debate. Accordingly, we have included multiple and regional perspectives on key topics to facilitate comparisons, especially at a global level, and provide rich materials for classroom debates. The ethics of commercial archaeology, for example, has individual entries that provide perspectives from Australia, Brazil, Japan, Nigeria, Southern Africa and the USA. While each entry provides an in-depth discussion of the issues that affect a particular region, taken together, these entries provide the materials required for students to undertake analyses of contrasts and comparisons at a global level.

The third challenge was to honor the work of archaeologists from throughout the world. The biographies in the encyclopedia were selected by section editors on the basis of the contribution of particular archaeologists to specific disciplinary areas and also through recommendations from archaeologists in

underrepresented countries. While we attempted to obtain some form of uniform global coverage in archaeological biographies, this was not possible as archaeology is at different stages of development in different parts of the world. The need to build archaeological capacity is greatest on the African continent. The small number of biographies of African archaeologists reflects the small number of archaeologists in the continent as a whole. While the vast majority of these archaeologists are located in South Africa, there are key nodes in countries such as Kenya and Nigeria. Sometimes these nodes are an outcome of capacity building that occurred as part of colonial processes, as with the life work of Charles Thurstan Shaw. Some biographies honor the work of archaeologists who spent their lives building capacity in a part of the world that is not their home country, as with the work of Betty Meggers in South America. All of the biographies provide insights into the life histories of archaeologists in various periods and in diverse parts of the world. Moreover, cultural attitudes are apparent in the profiles of biographies for each region. For example, while many Portuguese biographies are of mid-career archaeologists who are still alive, the majority of biographies of Japanese archaeologists are of people who established important facets of the profession and have now passed away.

The final challenge was to harness the potential of an online environment not only to ensure global accessibility but also to enrich the encyclopedia's content. From the beginning, the *Encyclopedia of Global Archaeology* was conceived firstly as an online reference work, and then as a print reference.

This interactive, online reference uses dynamic content to deepen discussions and to update material published in the print version, and to add information on new finds, or new ways of approaching the material. Hot links and extensive cross-references between keywords and related articles provide topics with greater depth and enable efficient searches in a user-friendly manner. The important innovation here is the continuous updating of entries and the addition of new entries to the eReference version. This will ensure that the encyclopedia maintains ongoing relevance.

Acknowledgments

My motivation to produce an encyclopedia originated in my childhood, when my mother, Annette Smith, used her hard-won wages to purchase weekly installments of the *Columbia Encyclopedia*, a one-volume encyclopedia produced by Columbia University Press. Each week, my sister, Jo, and I would take pleasure in discussing the newest entries with our mother. It was in these conversations that we learnt a love of scholarship. Decades later, in 2008, the genesis of the *Encyclopedia of Global Archaeology* arose out of a conversation between Teresa Krauss, a now very senior editor at Springer, and myself over lunch at a restaurant in Vancouver. Teresa drove much of the early conception of the encyclopedia. Later, I asked her "what is the best book you have commissioned?" She answered "Your encyclopedia." While this may seem as a complementary statement to make, it wasn't really. The *Encyclopedia of Global Archaeology* was Teresa Krauss' idea, not mine – so she was really congratulating herself! My first discussions with Teresa were followed by workshops and meetings in Atlanta, Dublin, Memphis, Hawaii, and, regularly, New York. It took five years to bring the first edition of this encyclopedia to fruition in 2014. In the six years since then, new chapters have been commissioned and existing chapters subject to continual updating. In the process, the *Encyclopedia of Global Archaeology* has become a much-loved constant in my daily workflow.

While this encyclopedia is much more than the sum of its parts, each of these parts have been essential to the final product. There are many people to thank. I am grateful to the individual authors, who have shared their knowledge and expertise. The vision and architecture of this encyclopedia has been steered by the International Advisory Board, while the untiring efforts of Section Editors have ensured that high quality and polished entries came in on time. In addition, I thank the members of our editing and production team, which includes all of the translators, but especially Lilén Malugani Guillet from Universidad Nacional de Catamarca in Argentina; administrative assistant for the first edition, Cristina Lanteri; in-house editors, Christine Hausmann for the first edition and Aparajita Basu for the second edition; my current editors at Springer, Michael Hermann, Andrew Spencer, and Christi Lue (Teresa Krauss, naturally, got promoted); and the managing editor for the first edition, Jo Smith. I am grateful especially to my husband, anthropologist Gary Jackson, who undertook the English language polish of many chapters. He encourages and guides me in all my projects, no matter how impossible they may seem when I start.

Those who seek insight into the role of the editor should look up the YouTube clipping "C is for Contrafibularity," from the BBC program Blackadder, in which the writer Samuel Johnson celebrates having completed his lifework of a dictionary with every word in the English language – only to be accosted by a host of new words. Like the English language, archaeology is constantly changing and growing. While this is the most globally comprehensive encyclopedia of archaeology produced to date, it is not possible to have an entry on every possible subject. People should use this encyclopedia as a first stop for obtaining information on a topic and as a directory to further specialist information. Those seeking greater knowledge on a specific topic should use the reading lists provided to identify specialist publications. Readers should be prepared for some of these readings to be in a language other than English.

The translated entries, which are a critical and definitive characteristic of this encyclopedia, have been made possible through support from Springer-Verlag and through two grants from Flinders University in South Australia, one from the Faculty of Education, Humanities and Law and one from the School of Humanity. This support has allowed the encyclopedia to contribute to the democratization of archaeology globally. By accessing the work of the finest scholars, no matter what language they write in, we have replaced English-language networks with multi-lingual, international networks and produced an encyclopedia that is truly global in scope.

About the Editor

Claire Smith is an anthropological archaeologist. She decodes patterns in human behaviors to interpret the past, understand the present, and envisage the future. The materials she analyzes range from rock art, statues, and monuments to memorials, graves, and social media. She has produced 13 books and more than 160 publications in English, Spanish, Catalan, Arabic, Russian, Portuguese, and Japanese. She is committed to intellectually enriching academia by strengthening the global impact of research by scholars from low-income countries. She has worked with the Aboriginal community of Barunga, Northern Territory, Australia, since 1990 and with Ngadjuri people in South Australia since 1998. Her current research interests are focussed on heritage, health, and well-being. In 2018, the Royal Anthropological Institute awarded Claire Smith the Lucy Mair Medal and Marsh Award, for sustained research with Australian Aboriginal communities that has contributed to human dignity.

Claire Smith is an anthropological archaeologist. She decodes patterns in human behaviors to interpret the past, understand the present, and envisage the future. The materials she analyzes range from rock art, statues, and monuments to memorials, graves, and social media. She has produced 13 books and more than 160 publications in English, Spanish, Catalan, Arabic, Russian, Portuguese, and Japanese. She is committed to intellectually enriching academia by strengthening the global impact of research by scholars from low-income countries. She has worked with the Aboriginal community of Barunga, Northern Territory, Australia, since 1990 and with Ngadjuri people in South Australia since 1998. Her current research interests are focussed on heritage, health, and well-being. In 2018, the Royal Anthropological Institute awarded Claire Smith the Lucy Mair Medal and Marsh Award, for sustained research with Australian Aboriginal communities that has contributed to human dignity.

Agriculture and Domestication

Dorian Q. Fuller is Professor of Archaeobotany at the University College London. He has worked on plant assemblages from many regions, including South Asia, West Asia, sub-Saharan Africa, mainland Southeast Asia, China, and parts of Europe, with a particular focus on Neolithic Archaeobotany and documenting plant domestication. He is also "Thousand Talents" Visiting Professor at Northwest University, Xi'an, China.

Archaeological Science

E. Christian Wells is Professor of Anthropology and Director of the Center for Brownfields Research & Redevelopment at the University of South Florida, where he has served previously as the Founding Director of the Office of Sustainability and as Deputy Director of the School of Global Sustainability. Wells, a Fellow of the American Association for the Advancement of Science, is an environmental anthropologist with expertise in archaeological science, especially as it pertains to the chemistry soils, clays, and other earthen substances.

Arleyn W. Simon is Associate Research Professor Emeritus at Arizona State University, Tempe. She directed the Archaeological Research Institute at ASU for 20 years, now CASR, in the School of Human Evolution and Social Change. She taught classes in Southwest ceramic analysis and museum collection management for 30 years. Her specialties are Southwestern Archaeology, particularly central Arizona, materials analysis, 3D modeling, and quantitative methods.

Archaeology in the Modern World

Paul R. Mullins is Professor in the Department of Anthropology at Indiana University-Purdue University, Indianapolis (IUPUI), Docent in Historical Archaeology at the University of Oulu (Finland), and Past President of the Society for Historical Archaeology (2012–2013). He is the author of *Race and Affluence: An Archaeology of African America* and *Consumer Culture (1999).*

John Schofield is Director of Studies in Cultural Heritage Management at the University of York, UK. Prior to his appointment at York in 2010, John spent 21 years in heritage protection and policy at English Heritage where he developed specialisms in contemporary, conflict, and landscape archaeology.

Archaeology of Art

Inés Domingo Sanz is ICREA Research Professor at the University of Barcelona and Vice President of the World Archaeological Congress. Her research explores the archaeologies of art from a multidisciplinary and a multiscale approach and it is currently funded by an ERC CoG Grant: LArcHer Project.

Danae Fiore graduated from UBA (Universidad de Buenos Aires, Argentina) and received her MA and PhD degrees from the University College London. Danae is currently a Researcher at CONICET (National Council of Scientific and Technological Research, Argentina) and an Associate Professor at UBA. Her main research interests are the archaeology of art, archaeological theory and methods, visual archaeology, and cultural heritage studies. Her work has mainly focused in regional projects in Patagonia and Tierra del Fuego, where she combines archaeological and ethnographic lines of research. She has published numerous papers in academic journals and chapters in edited books. Danee has co-edited four books and co-authored one. She has also published three books for children, several articles for the general public, as well as book chapters in school textbooks.

Ewa Dutkiewicz specializes in Paleolithic art studies. She is Curator of the Stone Age Department at Museum für Vor- und Frühgeschichte Staatliche Museen zu Berlin – Stiftung Preußischer Kulturbesitz in Berlin.

Bioarchaeology and Human Osteology

Soren Blau is the Manager of Human Identification and Senior Forensic Anthropologist at the Victorian Institute of Forensic Medicine. She is an Adjunct Professor in the Department of Forensic Medicine at Monash University; Founding Fellow of the Faculty of Science, The Royal College of Pathologists of Australasia; and recipient of a Churchill Fellowship (2013). Soren is also currently the Chair of the Forensic Anthropology Technical Working Group (National Institute of

Forensic Sciences, Australia) and a member of the INTERPOL Disaster Victim Identification Pathology and Anthropology Sub-Working Group.

Luis Fondebrider was born in Argentina, where he obtained his degree in Cs. Anthropological from the University of Buenos Aires (UBA). In 2014, he was distinguished by the UBA with the title of Doctor Honoris Causa. After the return of democracy to Argentina, in 1984, together with a group of students of archeology, anthropology, and medicine, and under the guidance of the American anthropologist Dr. Clyde Snow, he founded a non-governmental organization called the Argentine Team of Forensic Anthropology (EAAF) with the objective of scientifically documenting the human rights violations that had occurred in Argentina between 1976 and 1983. As a member of the EAAF, Dr. Fondebrider has participated as an expert before Argentine courts in more than 1,200 cases. EAAF has carried out investigative cases of political/ethnic violence in 50 countries around the world. Dr. Fondebrider, as a member of the EAAF, participated and/or co-led research and advisory missions in America, Africa, Europe, Middle East, and Asia-Pacific.

Douglas H. Ubelaker is a Curator and Senior Scientist at the Smithsonian Institution in Washington D.C. and served as the President of the American Academy of Forensic Sciences from 2011 to 2012. He has published extensively regarding his research interests in methods of extracting information from human skeletal remains and applications in forensic anthropology and bioarcheology.

Classical Archaeology

Jeffrey A. Becker is a Mediterranean archaeologist teaching at Binghamton University (State University of New York at Binghamton) in the USA. He also serves as an Editor for the Pleiades gazetteer and Smarthistory.org. His research centers on Roman architecture and urbanism.

Conservation and Preservation

Richard McClary completed his PhD at the University of Edinburgh in 2015, on Rum Seljuq Architecture, and then held a Leverhulme Trust Early Career Fellowship in Edinburgh, working on Qarakhanid architecture. Since 2019, he has been a Lecturer in Islamic Art and Architecture at the University of York. He has published two monographs and numerous articles and book chapters on medieval Islamic architecture and ceramics.

Douglas C. Comer has long experience in conducting research and developing management plans for protected areas, which he has done in every inhabited continent. He has published widely on archaeology, heritage and heritage management, as well as the use of aerial and satellite remote sensing technologies for the detection of heritage sites and environmental analysis and characterization. He is President of the United States National Committee of the International Council on Monuments and Sites (US/ICOMOS), Vice President of the ICOMOS Advisory Committee, Chair of the ICOMOS National Committee Council, and Immediate Past President of the ICOMOS Scientific Committee on Archaeological Heritage Management (ICAHM). He is also President of Cultural Site Research and Management, Inc., and President of the CSRM Foundation.

Cultural Heritage Management

Thanik Lertcharnrit is an Associate Professor of Archaeology and CRM Program Executive Board Member in the Department of Archaeology at Silpakorn University in Bangkok. He earned his BA with honors in Archaeology from the Department of Archaeology at Silpakorn University in Bangkok and MA and PhD degrees from the Department of Anthropology at Washington State University in Pullman, WA, USA.

Environmental Archaeology

Mike Morley is Associate Professor of Archaeological Science at Flinders University. He is a geoarchaeologist specializing in the reconstruction of past environments to contextualize archaeological narratives. Mike primarily works in Africa, Southeast Asia, and Australia, focusing primarily on the analysis of cave, rock-shelter, and fluvial sediments and what they can tell us about the habitats and environments that our Pleistocene ancestors interacted with. He is currently an Australian Research Council (ARC) Future Fellow, leading a project that aims to reconstruct the site and local environments that existed during periods of occupation and non-occupation of key archaeological and fossil sites in Pleistocene Southeast Asia and Australia. Mike uses a range of analytical techniques working at multiple scale, from micromorphology to geomorphology.

Ethics

Anna M. Kotarba-Morley is a Lecturer in Archaeology at Flinders University, Adelaide, South Australia. She is a Coastal and Maritime Archaeologist, Anthropologist, and Cultural heritage Expert with over a decade and a half experience in academia, museum, and consultancy sectors. Ania's extensive archaeological and heritage experience have been gained on sites in over 30 countries of the Near and Middle East, North and sub-Saharan Africa, South Asia, the Mediterranean, and the Black Sea, on numerous sites in the Northern and Western Europe, and recently in the Pacific Region, including in Australia and the Republic of Kiribati, Micronesia, and Remote Oceania. Ania is active in the field of teaching and research mostly connected with sustainability archaeology and risk preparedness and responses for cultural heritage sites and communities at risk of climate change and natural disaster.

Field Archaeology

Sandra Montón-Subías is an Archaeologist with broad interests in social and theoretical archaeology. She is currently an ICREA Research Professor at Universitat Pompeu Fabra (Barcelona, Spain), co-directs archaeological excavations in Guam, and investigates the intimate connection between material culture and gender in the making of the early modern colonial globalization. Sandra's recent publications include *Gender, Missions, and Maintenance Activities in the Early Modern Globalization: Guam 1668–98* (IJHA 2019), *Modern Colonialism, Eurocentrism and Historical Archaeology: Some Engendered Thoughts* (EJA 2018), *Archaeologies of Early Modern Spanish Colonialism* (Springer 2016), and *The Archaeology of Bronze Age Iberia: Argaric Societies* (Routledge 2014).

Bisserka Gaydarska is a specialist in Balkan and European prehistory with interests in archaeological method and theory, early urbanism, interdisciplinary studies, and identity.

Extreme Environments

Vivian Scheinsohn is Full Professor at the University of Buenos Aires and Researcher at the CONICET (Scientific and Technical National Research Council). She is directing an archaeological project in Patagonia since 2009.

Geographical and Cultural Overview Essays

Marcel Otte is mostly involved in the study of Upper Paleolithic Civilizations in the whole of Eurasia and especially their aesthetic and mythological aspects. He has been excavating different places across this region, from Portugal to Siberia. He is also interested in the mechanical evolution processes that explain human evolution – from the cultural behavior to the anatomy – by epi-genetic factors.

Historical Archaeology

Patricia Fournier was born in Mexico City. She has a PhD in Anthropology from the Universidad Nacional Autónoma de México. She is a Senior Professor of Archaeology at the Escuela Nacional de Antropología e Historia, Mexico City. She is specializes in Historical Archaeology, Ethnoarchaeology, and Archaeometry. Her recent publications include "Indigenous Charcoal Production and Spanish Metal Mining Enterprises: Historical Archaeology of Extractive Activities and Ecological Degradation in Central and Northern Mexico" in *Historical Archaeology and Environment*, edited by Marcos André Torres de Souza and Diogo Menezes Costa, Springer (2018); "Material Culture, Status, and Identity in Postindependence Central Mexico: Urban and Rural Dimensions" in *Colonial and Postcolonial Change in Mesoamerica: Archaeology as Historical Anthropology*, ed. by Rani T. Alexander and Susan Kepecs, University of New Mexico Press (2018).

History of Archaeology

Anke Hein is Peter Moores Associate Professor in Chinese Archaeology at the University of Oxford and a Fellow of St Hugh's College. She is an Anthropological Archaeologist focusing on prehistoric and early historic China, and her main research interests lie with identity formation and human–environment interaction in general as well as culture contact and ceramic technology in particular. She is currently involved in field projects on the eastern rim of the Tibetan Plateau and in Northwest China, and she is working on heritage data from the earliest excavations in Northwest China held in the Museum of Far Eastern Antiquities in Stockholm.

Human Evolution/Peopling of the World

Chen Shen is a Senior Curator of Chinese Art and Culture, currently serving as Vice President and Head of the Department Art and Culture at Royal Ontario Museum, Toronto, Canada, and is cross-appointed as Professor in the Department East Asian Studies, University of Toronto.

Hunter-Gatherer and Mid-range Societies

Anna Marie Prentiss is Regents Professor of Anthropology at the University of Montana, Missoula. Her research interests include evolutionary process, lithic technology, and development of indigenous fisher-hunter-gatherer traditions in North America's Rocky Mountains, Pacific Northwest, and Arctic regions. She has published over 75 peer-reviewed books, journal articles, and book chapters.

Indigenous Archaeology

Ndukuyakhe Ndlovu is a Senior Lecturer in the Department of Anthropology and Archaeology at the University of Pretoria. He completed his PhD at Newcastle University, UK. Ndukuyakhe has 20 years' experience in heritage management, during which he was employed by provincial as well as national heritage authorities. He later served on the councils of two heritage authorities. Ndukuyakhe is currently the Editor-in-Chief of the South African Archaeological Bulletin, Secretary for the World Archaeological Congress, and a Member of Council for the Association for Southern African Professional Archaeologists (ASAPA) and the South African Archaeological Society (SAAS).

Legislation

Angela M. Labrador is an Anthropologist with a background in Archaeology, IT, and Cultural Policy. Angela is a Managing Partner of Coherit Associates LLC, an international cultural heritage–consulting firm based in the USA. She is a certified Project Archaeology Master Teacher and has taught university courses and professional development workshops on topics related to heritage legislation, national frameworks for heritage inventories, and engaging the public in the stewardship of heritage resources. She recently co-edited *The Oxford Handbook of Public Heritage Theory and Practice* (2018), published by Oxford University Press.

Medieval and Islamic Worlds

Tadhg O'Keeffe is Full Professor of Archaeology at the University College Dublin. He has written and lectured extensively on medieval architecture, landscape, and settlement. He also maintains an active research interest in Historical Archaeology, Heritage Studies, and Archaeological Theory.

Alison Gascoigne is Associate Professor of Archaeology at the University of Southampton, UK, which she joined in 2007 following a PhD and Postdoctoral Research at the University of Cambridge. Her primary research interests concern cultural change in the Islamic-era Middle East, with a particular focus on urbanism and ceramic assemblages. She has extensive field experience particularly in Egypt, where she has recently completed a major survey of Tell Tinnis in the north Nile Delta. She has also worked in Cairo, in the Nile Valley, and in the western desert as well as in Afghanistan and Uzbekistan.

Museums

Sonia Archila obtained her PhD degree in 2000 from UCL, UK. At present, she is an Associate Professor in the Department of Anthropology, University of Los Andes, Colombia. Study of human–environmental interactions through time and social memory construction, particularly in relation to traditional knowledge of natural resource uses and archaeological heritage, are her main research interests.

Near East (Ancient, Pre-Achaemenid)

Laura Culbertson specializes in Ancient Near Eastern History Studies and Mesopotamian Studies in particular. She teaches in Middle Studies at American Public University.

Near East (Hellenistic and Roman)

Marta Żuchowska, Archaeologist and Sinologist, works as a Lecturer at the Institute of Archaeology, University of Warsaw. Between 1995 and 2010, she was a Member of the Polish Archaeological Mission at Palmyra, Syria. Her scientific work focuses on the issues of long-distance trade in Asia. She published many works concerning Palmyra and its special place in the trade of the Roman Empire.

Political and Social Archaeology

Uzma Z. Rizvi is Associate Professor of Anthropology and Urban Studies at the Pratt Institute, Brooklyn, NY, and a Visiting Professor at Shah Abdul Latif University, Khairpur, Pakistan. Rizvi's research interests include decolonizing archaeology, ancient urbanism, critical heritage studies, new materialism, and the postcolonial critique. A primary focus of her work contends with archaeological epistemologies and methodologies, and changed praxis based on decolonized principles and participatory ethics. Rizvi has intentionally interwoven archaeology with cultural criticism, philosophy, critical theory, art, and design.

Public Archaeology/Education

Marcia Bezerra is a Professor of Archaeology at the Universidade Federal do Pará in Brazil. Her research in the Amazon has covered themes like collecting, narratives of heritage, archaeology in popular culture, and teaching archaeology. She was the President of the Society of Brazilian Archaeology (SAB) and is a former WAC´s Southern America Junior Representative.

Mariana Petry Cabral is Professor of Archaeology at the Federal University of Minas Gerais (UFMG), Brazil. She has experience with indigenous archaeologies and collaborative projects, with extensive work in the Brazilian Amazon and indigenous history.

Religion and Sacred Spaces

Gary "Jacko" Jackson is a reluctant Anthropologist and Adventurer. He has worked with the Barunga Aboriginal community in the Northern Territory, Australia, since 1990. He also works with Ngadjuri people in South Australia. He is an Adjunct Senior Researcher at the College of Humanities, Arts and Social Sciences, Flinders University, South Australia.

Theory

Jordan Ralph is an Archaeologist who specializes in the archaeology of the contemporary past as well as Indigenous Australian archaeology. Jordan has worked in collaboration with people from Barunga, a remote Australian Aboriginal community, for a decade, where his research has focused on social justice and interrogating the material manifestations of government intervention.

Troy Lovata is a Professor in the interdisciplinary Honors College at the University of New Mexico in the USA, where much of his work has focused on the presentation of the past, the social role of material culture, and the cultural landscapes of the past and present. He earned a cum laude Bachelor of Arts in Anthropology from Colorado State University and both a Master of Arts and Doctorate in Anthropology, with a focus on Archaeology, from the University of Texas.

Underwater and Maritime Archaeology

Geoff Bailey is Anniversary Professor Emeritus of Archaeology at the University of York, UK, Visiting Professor at Flinders University, Australia, and Chairman of the EU COST Action "Submerged Prehistoric Archaeology and Landscapes of the Continental Shelf" (SPLASHCOS). His

research interests are in the archaeology of coastlines, submerged landscapes, and Quaternary landscape evolution, and he has led major projects in Australia, Greece, Saudi Arabia, and the UK. He is a Fellow of the Society of Antiquaries of London, Member of the Academia Europaea, and Corresponding Fellow of the Australian Academy of the Humanities.

Wendy van Duivenvoorde is an Associate Professor of Maritime Archaeology at the College of Humanities, Arts and Social Sciences, Flinders University, South Australia. She is an expert in late sixteenth- and early seventeenth-century Dutch shipbuilding. Her studies primarily focus on ships of exploration and Indiamen, and include the archaeological remains of Western Australia's Dutch East Indiamen shipwrecks. She has conducted research on the metal fasteners and anchors excavated from ancient Mediterranean merchantmen such as the Tektaş Burnu (±440–425 B.C.) and Kyrenia (third century B.C.) shipwrecks.

World Heritage

Vicky Kynourgiopoulou is Dean of Academic Affairs at Loyola University Chicago, Rome campus, and Professor of Cultural Heritage Studies. Since 2003, she is Chief Advisor at UNESCO and EU for the sustainable development of heritage sites, capacity building, and knowledge management in the Mediterranean and MENA region.

International Advisory Board

Neville Agnew has worked in the field of cultural heritage preservation in Australia and the USA for 40 years. He is a Principal Project Specialist with the Getty Conservation Institute in Los Angeles, California, where his projects deal with the conservation and management of archaeological sites, monuments, rock art, and outdoor sites in many parts of the world. He has a Ph.D. in chemistry.

Mitchell Allen is a Research Associate at the Archaeological Research Facility, UC Berkeley, and in the Department of Anthropology, Smithsonian Institution. He also runs Scholarly Roadside Service, a scholarly publishing consulting company, after founding and managing two independent archaeology-focused presses, AltaMira Press and Left Coast Press. Currently, he is writing up the results of a legacy survey project in Afghanistan, on which he was a field archaeologist in the 1970s.

Marius Alexianu is Associate Professor and former Head of the Ethnoarchaeology Section of the Arheoinvest Research and Training Platform at the "Al.I. Cuza" University of Iași, Romania. He has pioneered the ethnoarchaeology of salt in Europe. For 12 years, he led three extensive projects on the ethnoarchaeology of salt in Romania (2007–2019). Marius introduced the use of the saturated model in the field of ethnoarchaeology. He laid the foundations of the anthropology of salt discipline.

Dante Angelo teaches in the Department of Anthropology, Universidad de Tarapacá, Arica-Chile. His interests include: archaeological politics and theory, modernity, nationalism, and postnationalism.

Obarè Bagodo is the first Ph.D. qualified Archaeologist in the Republic of Benin. He is a Professor of Archaeology and Prehistory at the University of Abomey-Calavi, Benin, as well as the Director of the Laboratory of Art, Archaeology and Patrimonial Expertise (2012–2019) and the Coordinator of Master's and Ph.D. Programme in History and Archaeology in the Multidisciplinary Postgraduate School for Letters, Linguistics, Arts, Human and Social Sciences (2014 to October 2019) at the University of Abomey-Calavi.

Jane Balme studied Anthropology at the University of Western Australia and went on to complete a Ph.D. at the Australian National University on the lacustrine sites of lower Darling River, Western New South Wales, in 1990. She is now a Professor of Archaeology at the University of Western Australia. Her research is largely about the archaeology of Indigenous Australia. Her contributions over the years have been principally about the timing of first human colonization of Sahul, subsistence, adaptations to environments, the role and importance of perishable materials, the division of labor by gender in the past, and the meaning of symbolic objects (in particular beads).

Kate Clark is an Industrial Archaeologist with a career in museums and heritage in Australia and the UK, including Ironbridge Gorge Museums, English Heritage, the Heritage Lottery Fund, Sydney Living Museums, and Cadw in Wales. She is Visiting Professor of Heritage Valuation at the University of Suffolk and writes about archaeology, heritage management, and the many different ways in which we value heritage. Her new book,

Playing with the Past, contains around 80 creative workshop activities and games to help develop skills in heritage practice.

Margaret (Meg) Conkey is the Class of 1960 Professor Emerita of Anthropology at the University of California, Berkeley, CA, USA. She continues to publish aspects of Paleolithic art as well as gender and feminist research and carry out research on Upper Paleolithic hunter-gatherers, especially in the Pyrénées region of France.

Aedeen Cremin has degrees in Archaeology from the National University of Ireland (UC Dublin) and the University of Sydney, Australia. She taught European and Industrial Archaeology at the University of Sydney from 1978 to 2000 and directed fieldwork in North Portugal (the Vinhais Survey 1988–1994). From 2001 to 2015, she worked on Cambodian ceramics for the Greater Angkor Project.

Paulo DeBlasis is Archaeologist and Professor (Ph.D. in 1996, Full Professor in 2005) at the Museu de Arqueologia e Etnologia da Universidade de São Paulo (MAE-USP) and its Director since 2018. Besides involvement with archaeological research, he teaches Archaeological Theory, Brazilian Archaeology, and Pre-Colonial and Colonial Brazilian History and Archaeology, having previously held positions as Curator (1992–2006) and the Coordination of the Post-Graduation Program (2006–2008, 2012–2014). He has extensive experience on subjects ranging from rock art to heritage, intentional/ritual moundbuilding, settlement patterns, lithic studies, and archaic and formative societies.

Hui Fang is Dean of the School of History and Culture, Dean of the Cultural Heritage Research Institute, and Curator of the Shandong University Museum. His recent research areas include: Bronze Age Archaeology of China, Archaeological Theory and Archaeological History, and Cultural Heritage Protection. Currently, his main academic projects undertaken include: major project of National Social Science Foundation, translation project of National Social Science Foundation, and Sino-American Archaeological Cooperation project in Southeast of Shandong. He has won several awards and published extensively. He is on the Editorial Board of the *Journal of Archaeological Research*, *Asian Perspectives: The Journal of Archaeology for Asia and the Pacific*, and *Journal of World Prehistory.*

Caleb Adebayo Folorunso is a Professor of Archaeology at the University of Ibadan, Nigeria. His research interest is in the areas of ethnoarchaeology, historical archaeology, and cultural resources management. He runs a consultancy in archaeological impact assessment and mitigation. Caleb was at different times the Head of the Department of Archaeology and Anthropology, University of Ibadan, Nigeria, between 1995 and 2010.

Fekri A. Hassan (b. 1943, Cairo, Egypt) is Director of the Cultural Heritage Management Program, French University in Egypt, and Emeritus Petrie Professor of Archaeology at the Institute of Archaeology, University College London, England. He served as Vice President of the World Archaeology Congress, President of the International Water History Association, and Editor-in-Chief for 10 years of the *African Archaeological Review*. He taught at Washington State University, Pullman, USA (1975–1994), where he became a Full Professor in 1983. He obtained his Ph.D. in archaeology from Southern Methodist University (1973). His main interests and publications, including more than 250 papers, cover

archaeological theory, demographic archaeology, climate change, geoarchaeology, origins of civilization, origins of agriculture, water history, and cultural heritage management and development. Professor Hassan led and participated in 50 archaeological field expeditions.

Vladimir I. Ionesov is Professor and Head, Department of Theory and History of Culture; Director, International School for Advanced Research in Cultural Studies Samara State Institute of Culture; Founder and Chairperson, Samara Society for Cultural Studies; and Chairman, Regional Center on Urgent Anthropological Research in Samara, International Commission on Urgent Anthropological Research. His current interests include: Visual Communication; Ritual and Symbolic Transformations in Cultural Process: People and Things; The Ontological Parameters of World Heritage: "Trace," "Sign," "Memory," "Folk art," and "Creativity." He has published more than 350 scientific works, including five monographs and over 25 edited books.

Charles Andrew Ivey French is Professor of Geoarchaeology in the Department of Archaeology at the University of Cambridge and Director of the McBurney Laboratory, which specializes in the analysis of past landscapes and human impact in many parts of the world using geoarchaeological and micromorphological techniques.

Matthew Johnson is Professor of Anthropology at Northwestern University. He works on medieval and historical archaeology of Europe in its Atlantic setting. He has written six books on a range of themes, including castles, traditional houses, landscape, and an archaeology of capitalism. His best known book is *Archaeological Theory: An Introduction*, the revised third edition appeared in 2019.

Alok Kumar Kanungo is Assistant Research Professor at the Indian Institute of Technology (IIT) Gandhinagar, India. His early childhood experiences of growing up in close contact with indigenous communities of Eastern and Northeastern India led him to focus on archaeological and ethnographic studies of indigenous and ancient technology. He has documented the rich heritage of the Nagas of Northeast India, and the Bondos and Juangs of Odisha both in the field and in museums across Europe and United Kingdom. He has published extensively on glass and glass-bead production, including writing or editing 14 books and 65 research articles. He has lectured at universities and research institutes across the world and has been the recipient of several prestigious awards including the Humboldt, Fulbright, and Homi Bhabha Fellowships.

Charles C. Kolb is an Independent Scholar and Senior Program Officer (retired), National Endowment for the Humanities (USA). He has a Ph.D. from The Pennsylvania State University on Archaeological, Ecological, and Ethnoarchaeological Research in Central Mexico, Central Asia/Afghanistan, North American Great Lakes, and East Africa. He is a specialist in ceramic physiochemical analysis. Charles is Editor or editor of 6 monographs, over 130 peer-reviewed articles and book chapters, and more than 800 book reviews. He has also been a contributor to 16 encyclopedias. He has been Associate Editor of the Society for Archaeological Sciences Bulletin since 1986. Charles is a former university anthropology professor (24 years), director of research and grants (six years), and federal government grantsman (23 years).

Thanik Lertcharnrit is an Associate Professor of Archaeology and CRM Program Executive Board Member in the Department of Archaeology at Silpakorn University in Bangkok. He earned his BA with honors in Archaeology from the Department of Archaeology, Silpakorn University, Bangkok, M.A. and Ph.D. degrees from the Department of Anthropology, Washington State University in Pullman, WA, USA.

William D. Lipe is Professor Emeritus of Anthropology at Washington State University, Pullman, Washington, USA. He is a former President of the Society for American Archaeology and a current Board of Trustees Member of the Archaeological Conservancy and the Crow Canyon Archaeological Center.

Arkadiusz Marciniak is Professor of Archaeology at Adam Mickiewicz University in Poznań in Poland. His expertise is in the development of early farming communities in Western Asia and Central Europe and their progression to complex societies. His other interests comprise zooarchaeology of Neolithic farming communities as well as heritage pedagogies and contemporary challenges of heritage policies and strategies.

Rafael Guedes Milheira has a Ph.D. and Master's degree in Archaeology from the Museum of Archaeology and Ethnology at the University of São Paulo and a degree in History from the Federal University of Pelotas, and is also a Postdoctoral Researcher in Archaeology at the University of Exeter, England. Currently, he is Associate Professor in the Department of Anthropology and Archaeology at the Federal University of Pelotas. He is also a permanent Professor and current Coordinator of the Graduate Program in Anthropology at the Federal University of Pelotas (Master and Doctorate) and Collaborating Professor of the Graduate Program in Cultural Heritage at the Federal University of Santa Maria. He has a Research Productivity scholarship, level 2, from CNPQ. He is Coordinator of the LEPAARQ-UFPel Teaching and Research Laboratory in Anthropology and Archaeology and leader of the homonymous research group at CNPQ. In addition, he was coordinator of the Southern Regional Nucleus of the Brazilian Archeology Society (2015–2016). He is also Editor of the journal *Cadernos do LEPAARQ* and the *Journal of Archeology* of the Society of Brazilian Archeology, (2018–2019 and 2020–2021). He works with

archaeology of the pre-colonial populations of the Pampa and the South-Brazilian coast, Landscape Archeology, GIS applied to Archaeology, Archaeological Heritage and Theory, and Method in Archaeology.

Margaret Miller specializes in the archaeology and material culture of the ancient Mediterranean. She publishes widely on cultural relations between first millennium BC Greece, Anatolia, and the ancient Near East, especially relations within and with the Persian Empire. She has a long-standing interest in the exploitation of archaeology as a tool of social history, whether Greek drama or domestic life.

Koji Mizoguchi is Professor of Archaeology in the Faculty of Social and Cultural Studies, Kyushu University, Japan. He is the current President of the World Archaeological Congress. His research topics and areas cover social archaeology, archaeological theory, the Yayoi and Kofun periods of Japan, the Neolithic and the Bronze Age of Europe, and the Shang dynastic period of China.

Dídac Román Monroig has a Ph.D. in Prehistory from the University of Valencia. He is currently an Excellence Researcher at the University Jaume I (Castelló). His research is focused on the study of Palaeolithic, Mesolithic, and rock art in Western Europe. He has directed excavations at more than ten Palaeolithic and Mesolithic sites throughout the Iberian Mediterranean basin. He has also led many research projects on these topics and published more than 90 papers.

Sonia Archila Montañez obtained her Ph.D. degree in 2000 from UCL, UK. At present, she is an Associate Professor in the Department of Anthropology, University of Los Andes, Colombia. Study of human–environmental interactions through time and social memory construction, particularly in relation to traditional knowledge of natural resource uses and archaeological heritage, are her main research interests.

George P. Nicholas is Professor of Archaeology at Simon Fraser University and is Co-Principal Investigator on several international research projects. He is an Adjunct Faculty Member in Archaeology at Flinders University in Adelaide, South Australia, and Visiting Professor, Center for Ainu and Indigenous Studies, Hokkaido University, Japan. His current work investigates intangible heritage, indigenous archaeology, and traditional knowledge and archaeology and promotes heritage as a human right and archaeology as a tool of social justice.

Muiris O'Sullivan is Emeritus Professor of Archaeology at the University College Dublin where he formerly served as Head of the UCD School of Archaeology.

He has published extensively on passage tombs and prehistoric rock art and was the Lead Archaeological Consultant for the recently launched new visitor experience at Brú na Bóinne a UNESCO World Heritage Site incorporating the great passage tomb complexes at Newgrange, Knowth, and Dowth. He also serves on the Comité Scientifique for Paysages de Mégalithes de Carnac et du Sud Morbihan in France. He was appointed to the Irish Heritage Council in 2016.

Luiz Oosterbeek is Professor at the Polytechnic Institute of Tomar, Principal Investigator of the Quaternary and Human Adaptations Cluster of Geosciences Centre at Coimbra University, and Secretary General of the International Council for Philosophy and Human Sciences. His research interests include origins of farming, rock art, heritage, landscape management (in Portugal, Africa, Latin America). He is the Editor of over 300 papers and 50 books. He is also former SG of UISPP and UNESCO Chair Holder of "Humanities and Cultural Integrated Landscape Management."

Charles E. Orser Jr., is an Anthropological Historical Archaeologist who investigates the modern world as it was created after about 1492. He is the Editor of over 90 professional articles and several books, most recently *An Archaeology of the English Atlantic World, 1600–1700* (Cambridge University Press, 2018). He is the Founder and Editor of the *International Journal of Historical Archaeology*, and in 2019, he received the Society for Historical Archaeology's highest award, the J. C. Harrington Medal, for lifetime achievement in the discipline.

Dario Piombino-Mascali is a Research Professor at Vilnius University, Lithuania. He is a Bioarchaeologist who specializes in mummy studies. In 2007, he was awarded a Doctorate in Paleoanthropology and Pathocoenosis from Pisa University. In 2008, Dario was appointed as a Senior Researcher in Paleopathology at the European Academy of Bolzano. Two years later, he became the Scientific Curator of the Capuchin Catacombs of Palermo. He joined Vilnius University in 2013 as a Visiting Scholar in Anatomy, Histology, and Anthropology and was promoted to Research Professor in 2018. Dario has published extensively in the areas of biological and forensic anthropology as well as in bioarchaeology, and has investigated a wide

range of human remains, including the South Tyrolean Iceman, the mummies found in several European crypts and churches, Egyptian mummies, old anatomical specimens, and the so-called "fire mummies of the Philippines. Dario is a also specialist for the study and conservation of Catholic relics.

Gustavo G. Politis obtained his Ph.D. from Universidad Nacional de La Plata, Argentina, in 1984. He is currently Researcher at the Consejo Nacional de Investigaciones Científicas y Técnicas de Argentina (CONICET) and Professor at the Universidad Nacional del Centro de la Provincia de Buenos Aires and at the Universidad Nacional de La Plata, Argentina. He has published five books (including Nukak. Ethnoarchaeology of an Amazonian People, UCL Series, Left Coast Press 2007) and edited another six (including Archaeology in Latin America, Routledge 1999). Gustavo has also published more than a hundred and forty articles in peer-reviewed journals and book chapters. His main research interests are the archaeology of the Pampas of Argentina, the expansion of Homo sapiens in South Americas, and the ethnoarchaeology of South American hunter-gatherers. Gustavo is also interested in archaeological theory and in the sociopolitics of archaeology in Latin America.

Nathan Schlanger, Professor of Archaeology at Ecole Nationale des Chartes, Paris, is researching and publishing on material culture studies, on archaeological heritage management, and on the history and politics of archaeology.

Stephen Shennan is Professor of Theoretical Archaeology at the UCL Institute of Archaeology, where he was Director 2005–2014. His main interest is explaining stability and change in prehistory in the light of evolutionary ideas. He has published over 120 papers and books, including *Quantifying Archaeology* (2nd edition 1997), *Genes, Memes and Human History* (2002), and T*he First Farmers of Europe: An Evolutionary Perspective* (2018). He is a Fellow of the British Academy and a Member of the Academia Europaea. He received the Rivers Medal of the Royal Anthropological Institute in 2010 and a Shanghai Archaeological Forum Research Award for his EUROEVOL project in 2015.

Ladislav Šmejda is an Associate Professor in the Department of Anthropology, University of West Bohemia in Pilsen, Czech Republic. His research interests span from mortuary practices and spatial analysis of archaeological data to ethnoarchaeology and human ecology.

Sharon Sullivan is an Australian Archaeologist and Advocate of Indigenous Australian Rights. She has written five books on heritage management. Sharon is best known for her work in establishing protocols and programs for cultural heritage management in Australia, most notably through The Burra Charter: The Australia ICOMOS Charter for Places of Cultural Significance.

Henry Tantaleán is Professor at the National University of San Marcos, Lima, Peru, and Co-Director of the Chincha Archaeological Program. His research interests include Andean archaeology, theoretical archaeology, origins of the prehistoric state, and relation between archaeology and politics.

Sandra L. Lopez Varela is a Professor at the Universidad Nacional Autónoma de México, holding a position in HeritagePpreservation and Management in the Faculty of Philosophy and Letters. As an Anthropological Archaeologist, her recent research adopts a critical approach to economic and development growth policies to combat poverty in Mexico, which has endowed her with the Friedrich Wilhelm Bessel-Forschungspreis Award of the Alexander von Humboldt Foundation. Her publications approach heritage in land-use plans, planning and development, public policies, indigenous populations, and business and marketing.

Karen D. Vitelli retired from the Anthropology Department at Indiana University, Bloomington, in 2005 and now lives in Mid-Coast Maine. She was on committees that wrote the professional codes of ethics for the SAA and AIA and edited several of the early books on archaeological ethics. She currently directs the Franchthi Cave, Greece project, overseeing final publications.

Sussane Voss studied Egyptology, Classical Archaeology, and Ancient Near Eastern Studies in Berlin and Heidelberg. Since 2006, she has been directing scientific projects about the "History of German Egyptology and Archaeology in Egypt."

Patty Jo Watson is the Edward Mallinckrodt Distinguished University Professor Emerita of Archaeology at Washington University in St Louis. She was a leader in the development of processual archaeology and one of the first female professors of archaeology in the USA. Her research interests focus on subsistence, technology, economy, and the environment.

Qiaowei Wei is Associate Professor at Shanghai University. His research interests include Chinese archaeology, public archaeology, and cultural heritage management.

H. Martin Wobst is Professor Emeritus of Anthropology at the University of Massachusetts at Amherst, Massachusetts, USA, where he taught from 1971 to 2012. His work focused on theory and method in anthropology and anthropological archaeology and how they influence each other, and the people they are designed to explain, both in the past and present. He is interested in how material culture constructs and constrains individuals, communities, and societies, how the work of anthropologists has contributed to all aspects of the modern world, and how anthropologists can help to enlighten us on alternative material constructions of society to those in which they are embedded.

Thomas W. Wyrwoll is a German Archaeologist, Anthropologist and Zoologist. He heads the Institute for Mammalogy and Anthropology with its attached Laboratory for Archaeoiconological Biology and presides over the German Society for Rock Art Research. As an expert in prehistoric art, in particular rock art, he is known for his work on animal and human depictions. His research focuses on the Old World, chiefly Europe, the Eurasian Steppe Belt, and the Saharo-Arabian region.

Ege Yildirim is an Urban Planner specializing in heritage conservation and management with over 20 years of experience working in Turkey and internationally. Based in Istanbul as an independent consultant and lecturer, she currently serves as the ICOMOS Focal Point for the UN Sustainable Development Goals.

Luca Zan is active in the field of management and accounting history, and the management of arts/heritage organizations. He carried out fieldwork in China, Turkey, Peru, and Ecuador, in addition to Europe. He is also involved in arts management education and was Founder and past Director of GIOCA, Unibo, till 2020 and Adjunct Faculty at CMU, Pittsburgh (2005–2020), and CAFA, Beijing.

Larry J. Zimmerman is Professor Emeritus of Anthropology and Museum Studies at Indiana University-Purdue University Indianapolis. In 2008, he received the inaugural Peter J. Ucko Medal from the World Archaeological Congress and in 2020, the Lifetime Achievement Award from the Society for American Archaeology. His publications and research include repatriation, Indigenous Archaeology, ethics, and the archaeology of homelessness.

Abu Hureyra: Agriculture and Domestication

Andrew M.T. Moore
Rochester Institute of Technology, Rochester, NY, USA

Introduction

The prehistoric settlement of Abu Hureyra (35° 52′ N, 38° 24′ E) was located on the edge of the valley of the Euphrates River in northern Syria. It was a very large (11.5 ha) mound composed of two superimposed villages, Abu Hureyra 1 (c. 13,500–11,500 CalB.P.) and Abu Hureyra 2 (c. 10,600–7500 CalB.P.), linked by an intermediate episode of occupation (c. 11,500–10,600 CalB.P.) (Moore et al. 2000: Fig. 14.1). The site was thus continuously inhabited for 6000 years. Culturally, Abu Hureyra 1 had late Epipalaeolithic affinities, while the Intermediate Period and Abu Hureyra 2 fell within the Neolithic of Western Asia.

Key Issues

The site was excavated in 1972 and 1973 as part of an international salvage campaign that preceded the completion of a dam across the Euphrates (Fig. 1). The site was flooded in 1974. Seven trenches were dug across the site to establish the sequence of occupation. These demonstrated that the initial settlement of Abu Hureyra 1 was confined to the northwest sector of the mound. The bulk of the deposits was derived from the much more extensive settlement of Abu Hureyra 2.

All the soil was dry sieved to ensure near total recovery of artifacts and animal bones. Given the potential of the site to yield information about the formative stages of agriculture, the excavators systematically employed flotation to recover large samples of plant remains. The 2 t of animal bones and 500 l of plant remains retrieved by these methods provided important insights on changes in the economy and environment.

The initial settlement at Abu Hureyra in Period 1A consisted of multi-chambered pit dwellings dug into the subsoil that were covered with a timber framework and roofed with reeds (Fig. 2). This settlement was occupied year-round and lasted for 500 years. The form of the settlement changed abruptly in Periods 1B and 1C. The inhabitants built their huts on the surface of the ground with a frame of wooden posts and floors of trodden earth or clay. Finds of human bones suggested that some of the deceased were buried within the settlement.

The most numerous artifacts were made of chipped stone. Microliths, especially large lunates, and also scrapers and notched pieces, were conspicuous. A few fragments of obsidian were imported from Anatolia to the north. The bone artifacts included bipoints used as arrowheads, many awls, and some pins. Many of the

other tools were made of basalt, among them grinding dishes, querns, rubbing stones, pestles, and mortars. These were used to prepare food and to grind pigments. Notched pebbles were probably used as sinkers for fishing lines and nets.

The inhabitants of Abu Hureyra 1A were hunters and gatherers who consumed a diverse range of foods. They collected over 100 species of edible plants (Moore et al. 2000: 369), of which wild cereal grains, feather grasses, club rush, knotgrass, millets, and chenopods were staples. Persian gazelles were the main source of meat. Herds of these animals were hunted using animal traps as they migrated past the site in the spring. The meat from these gazelles was probably dried for consumption later in the year (Legge and Rowley-Conwy 2000: 449, 450). The other main game animals were onagers, wild cattle, sheep, and hares.

Abu Hureyra: Agriculture and Domestication, Fig. 1 The prehistoric settlement mound of Abu Hureyra from the southwest

An abrupt change in economy took place in the transition from Period 1A to 1B, c. 12,900 CalB.P. The sudden onset of the Younger Dryas climatic phase caused a prolonged drop in temperature and increase in aridity that significantly altered the environment (Robinson et al. 2006: 1536). Many of the staple plant foods diminished in abundance. The villagers responded by adopting farming (Moore et al. 2000, 479; Hillman et al. 2001). Among their crops were domestic rye, einkorn, and lentils. Cultivation of crops provided increasing amounts of food thereafter, and the population of the settlement grew as a result. The inhabitants

Abu Hureyra: Agriculture and Domestication, Fig. 2 A reconstruction drawing of a pit dwelling in the village of Abu Hureyra 1A

Abu Hureyra: Agriculture and Domestication, Fig. 3 The village of Abu Hureyra 2 as it would have looked c. 9000 CalB.P.

continued to hunt gazelle as before but they modified their pattern of plant gathering.

New evidence from across the northern hemisphere indicates that the Younger Dryas was precipitated suddenly by a cosmic event, likely caused by a comet or asteroid, which fragmented in the atmosphere (Bunch et al. 2012; Firestone et al. 2007; Wittke et al. 2013). This triggered a meltwater pulse into the North Atlantic that caused the onset of much cooler, drier conditions (Broecker 2006). This cosmic event is signalled by the widespread occurrence of platinum in terrestrial deposits dating to the beginning of the Younger Dryas (Moore et al. 2017). Evidence from Abu Hureyra indicates that an airburst from the asteroid or comet occurred within a kilometer or two of Abu Hureyra itself, causing the incineration of the Period 1A village c. 12,900 CalB.P. (Moore and Kennett 2014). The survivors of this catastrophe refounded the Abu Hureyra 1 village, this time with huts built above ground. It was they who, in a severely altered environment, took up farming.

During the Intermediate Period and Period 2, the nature of the settlement changed remarkably. The houses in this densely packed village were built of mudbrick, were rectilinear in plan, and contained several rooms. Following the development of farming, the settlement grew very large until in Period 2B its population numbered between 5000 and 6000 (Fig. 3). Its economy was based on an array of cultivated cereals, rye, several wheats and barley, and legumes, including lentils, peas, vetches, and chickpeas. The villagers also raised flocks of sheep and goat while continuing to hunt gazelle. Then, in the transition from Period 2A to 2B, c. 9300 CalB.P., hunting of gazelle sharply declined because of overexploitation. The inhabitants maintained the meat supply by rapidly expanding their flocks of sheep and goats and adding domestic cattle and pigs to the mix. By this time, hunting and gathering had ceased to contribute much to the diet.

The artifacts in Period 2 were significantly different from those of Period 1. The chipped stone industry was composed of large tools on blades, notably arrowheads, burins, and end scrapers, with a few sickle blades. Many of these artifacts were used to kill and butcher game. Small but regular amounts of obsidian attested to continued long-distance contacts with central and

eastern Anatolia. Bone tools, including awls, needles, and spatulae, were used in basketry, leather working, cooking, and as ornaments. There were relatively few ground stone tools in Period 2, so most agricultural and food-processing implements were presumably made of wood and other perishable materials.

Conspicuous among the remains from Period 2 were burials of humans. These were usually single inhumations or, occasionally, group burials in shallow graves under the floors of houses (Moore and Molleson 2000: 278). More women than men were buried in these locations, indicating a strong link between women and the home. Skulls were often buried separately from the rest of the corpse. The burials were the final stage in a lengthy series of rituals involving sequestering of the body while the flesh decayed. These elaborate burial rites reveal a rich ideology with reverence for ancestors and belief in an afterlife.

Many of the skeletons were sufficiently well preserved to yield vivid evidence of the lives these people had led. Most exhibited traits that indicated that they had worked extremely hard. The females, in particular, had developed a series of injuries caused by spending many hours of the day grinding grain on a saddle quern for food (Molleson 2000: Fig. 11.8).

Abu Hureyra is significant because it documents the transition from hunting and gathering through a continuous sequence of occupation at a single site. Year-round sedentary life based on specialized hunting and gathering preceded the transition to farming. The transition itself was precipitated by an abrupt climatic change, the onset of the Younger Dryas. The Younger Dryas was caused by a cosmic impact that devastated Abu Hureyra itself. The survivors among the inhabitants went on to develop farming. The subsequent expansion of agriculture was a lengthy step-by-step process that culminated 5000 years later in a mature mixed farming system. The inception of farming had extraordinary consequences at Abu Hureyra, from the massive growth in the population of the village to its impact on the people themselves.

Abungu, George H.O.

Ndukuyakhe Ndlovu
Department of Anthropology and Archaeology, University of Pretoria Hatfield, Pretoria, South Africa

Basic Biographical Information

George H. O. Abungu, a Kenyan, is among some of the well-known African archaeologists. He has had a tremendous academic career, establishing himself as one of the leading heritage professionals who have played a pivotal role in the management of Africa's rich past. His illustrious career should be an inspiration to the younger generation of African scholars who take up an interest in the discipline of archaeology and heritage management.

George trained as an archaeologist at the University of Nairobi Kenya between 1980 and 1984 with an Honors degree in archaeology and was subsequently employed as a Research Trainee with the National Museums of Kenya (NMK). A year later, in 1985, he got a scholarship to study at Cambridge University in England, United Kingdom, where he received an M.Phil. (1986) and a Ph.D. (1989) in archaeology. His Ph.D. research was titled *Communities on the River Tana: An Archaeological Study of Relations Between the Delta and River Basin, AD 700–1890*.

Dr. George Abungu went back to Kenya and continued working for the NMK as a Coastal Archaeologist. Between 1984 and 2002, he served in a number of positions beginning as a Research Trainee in 1984; a Senior Research Scientist 1987–1990; Head, Department of Coastal Archaeology 1990–1995; Head, Coastal Museums Programme 1992–1995; Deputy Director, NMK 1996–1997; and a Director, Regional Museums, Sites, and Monuments 1997–1999 and the Director General of the NMK, 1999–2002 when he left NMK.

Besides working for the NMK for almost two decades, Dr. Abungu has had many other professional responsibilities over the years, among them, Founding Chairman of Africa 2009 Program, and Founding Chairman for the Centre for Heritage Development in Africa (CHDA). He was a Research Associate (2001–2009) with the Field Museum of Natural History in Chicago, a Committee Member and African Representative on the ICOMOS International Committee on Underwater Cultural Heritage, and a Kenyan Representative on the UNESCO World Heritage Committee (2005–2009). Other positions of responsibilities he has held include World Archaeological Congress (WAC) Council Member from 1997, Chairman of the International Standing Committee on the Traffic of Illicit Antiquities (since 1999), Global Heritage Fund Advisory Board Member (from 2002), Member of the Executive International Council of Museums 2004–2010, and Vice-President of International Council of Museums (ICOM) from 2010.

In well over two decades, Dr. George Abungu has actively worked to ensure that the preservation of the rich African heritage and training of heritage professionals including heritage managers is not only enhanced but well established. His knowledge has been sought after, and he is often a key note speaker to many international conferences as well as guest lecturer to a number of universities, in Africa and beyond. Dr. Abungu's efforts have not gone unnoticed and most recently became the recipient of the

2012 Association for Research into Crimes Against Art (ARCA) Award for Lifetime Achievement in Defense of Art 2012 as well as the recipient of *Knight in the Order of Arts and Letters of the French Republic*. He is also a recipient of the *Life Prize in Museology* (2007), as well as *Passeur du Patrimone*, of Ecole du Patrimone Africa (2009).

The Kenyan authorities have also honored this high achiever as he is one of the three professionals whose contributions were celebrated by the NMK during its centenary celebration in 2011. In particular, Dr. Abungu was honored for the contribution he made to research and the development of Coastal Archaeology in Kenya.

Besides being a museum professional and training many aspiring heritage professionals, Dr. Abungu has been a scholar of note. He has published extensively and his publications have covered a wide range of subjects, from archaeology, heritage management, heritage legislation, to museology. He is currently undertaking research on one of the most significant challenges in this century, that of the relationship between heritage conservation and development. In the case of an African continent that lags behind in service delivery to its citizens, the conflict between managing Africa's rich past and encouraging development has become a big challenge. Additionally, Dr. Abungu is an Editorial Member for among other publications, *Public Archaeology* and *African Archaeological Review*.

He is a Founding Director of the Okello Abungu Heritage Consultants, a company, through which he offers specialized expertise to a number of heritage institutions in Africa and beyond, particularly in the areas of heritage management and planning, training, and policies relating to the management of World Heritage sites and heritage training programs in the field of world heritage in and out of Africa.

Major Accomplishments

As a trainer, mentor, and advisor, Dr. Abungu has been instrumental in efforts to improve the management of World Heritage and other sites in Africa. He is among the scholars who have pushed the African position at the World Heritage Committee (WHC) and other international forums to ensure that the rich heritage of the continent is adequately represented on the World Heritage List and supported. Among some of his accomplishments in this area has been the writing of Management Plans for Lalibela WHS (Ethiopia), Kilwa Kisiwani and Sogo Mnara WHS (Tanzania), Robben Island (SA), and nomination dossiers for Mijikenda Kaya (Kenya), the Kenya Rift Valley Lakes System (Kenya), and Le Mourne (Mauritius) among others. He is also the Founding Coordinator for the World Heritage Nomination Course in Africa 2008–2012 and the African Regional Coordinator for the UNESCO African Periodic Reporting 2010–2011. Both of these exercises have not only led to the increase of the number of African heritage sites on the UNESCO World Heritage List but also to the improvement in the conservation of the heritage in Africa.

An advocate against the illicit trade in African heritage, Dr. Abungu was recently recognized for his commitment to this through the 2012 ARCA award. He was instrumental in the return to Kenya of the looted vigango, which are the traditional grave markers. Many of these traditional grave markers were stolen from the Mijikenda Kayas, which are now on the World Heritage List. Their return followed a process of repatriation Dr. Abungu began with his American colleagues many years ago when he worked on Kenya's Coastal Archaeology and as the Director General of the National Museums of Kenya.

Académie Internationale de la Pipe

Peter Davey
School of Histories, Languages and Cultures, University of Liverpool, Liverpool, UK

Basic Information

The *Académie Internationale de la Pipe* is a learned society which, according to its statutes, was established "to advance the education of the public in the economic and social history of tobacco and pipe smoking worldwide." Specifically it attempts to promote a better awareness of the tobacco pipe as a cultural, artistic, and social phenomenon and to highlight the particular place the pipe holds in the history of people and civilizations. It supports and encourages the collecting of both artifacts and documentary information about pipe smoking and encourages serious research on pipes and related subjects.

The Academy came into being in 1984 on the initiative of a Frenchman, André-Paul Bastien. Initially based in Italy, it moved to France in 1992. Membership of the Academy consists of three distinct constituencies: serious collectors of pipes and tobacco-related artifacts, curators of national museum and specialists of museum collections, and academics involved in the study of the archaeology and socioeconomic history of tobacco and smoking. Originally, the Academy might be described as elitist in that only two academicians were permitted from any one country and applications were intensively vetted. There was a secondary layer of "corresponding" members as well as institutional and sponsor involvement.

In 2008 the Academy moved its head office to Liverpool where it is housed within the School of Archaeology, Classics and Egyptology at the University, under new charitable articles of association (UK Registered Charity Number 1126166). Its address is 12–14 Abercromby Square, University of Liverpool, L69 7WZ. Its website can be found at www.pipeacademy.org. Under its new articles, there is a single category of individual membership which is now open to any bona fide researcher and can include any number of people from the same country, including women.

Major Impact

The Academy has always tried to promote knowledge and research about tobacco pipes and their use in every era, in all parts of the world and from every angle, whether cultural, artistic, scientific, sociological, or ethnographic. It does this in three main ways: by organizing conferences at different centers at which members are able to discuss major themes, by the formation and activities of

working groups of members, and by a program of publication.

Since 2008 there have been conferences in Hungary (2009), France (2010 and 2014), Serbia (2011), Poland (2012), Germany (2013), Belgium (2015), Japan (2016), UK (2017) and The Netherlands (2017). The conferences are usually focused on regional pipe collections and are intended to promote research and local appreciation of them. For example, the Budapest conference resulted in a series of papers on the archaeology of the clay pipe in Hungary and eastern Europe which, together, have transformed understanding of the industry in that region (Ridovics and Davey 2010). At Grasse, the meeting focused on the outstanding pipe collection brought together by A Baroness Rothschild in the second half of the nineteenth century. The 2011 conference stimulated research into pipe collections throughout Serbia (Gačič 2011). In 2015 the meeting was based in the Nationaal Tabaksmuseum Wervik, Belgium, with the express purpose of focusing attention on the role of tobacco and smoking behavior during the First World War (Gallagher 2016). In 2016 the conference took place in the Tobacco and Salt Museum in Tokyo and considered the spread of tobacco and smoking habits to the Far East and their local manifestation in the context of one of the finest tobacco-related museum collections in the world.

Between 1996 and 2008, the Academy regularly published the *Livre de la Pipe* in French, English, and German. It also produced 19 issues of an annual newsletter the *Annales* from 1987 to 2006 and other occasional publications (e.g., Suzuki 1997).

Since the move to Liverpool in 2008, the Academy has launched a new A4, full-color, peer-reviewed annual journal that is now the main public platform for pipe research worldwide. So far 9 volumes with 116 separate articles totalling 1366 pages have been published. Contributions range from overviews of national and regional clay pipe production (e.g., Davey 2009), art historical studies (e.g., Burla et al. 2011), social and economic conditions of workers in the pipe industry (e.g., Stam 2015), and the analysis of archaeological groups from around the world (e.g., Leenen 2013; Gellichi and Sabbionesi 2015; Bekić 2016).

Acheulean Industrial Complex

Kathleen Kuman
School of Geography, Archaeology and Environmental Studies, University of the Witwatersrand, Johannesburg, South Africa

Introduction

For almost a million years in Africa during the first phase of human cultural development known as the Oldowan industrial complex, there appears to have been limited directional change in tool

technology. As sophisticated and variable as that technology had been, many archaeologists consider it a time of relative technological stasis, with differences across assemblages being relatively minor. Although the success of the simple core and flake adaptation was evident in its long endurance, by 1.7 Ma, innovations began with the appearance of the Acheulean. An adaptive and technological threshold was crossed with the knapping of large flakes (>10 cm in size) and the shaping of heavy-duty tools (handaxes, cleavers, and picks) for specific tasks. The Acheulean industrial complex, together with the Oldowan, is referred to as the Earlier Stone Age (ESA) and persisted until c. 0.3/0.25 Ma in Africa. Mary Leakey (1971) published the first detailed description of the Early Acheulean, using the EF-HR assemblage from Olduvai Gorge as her descriptive type series. Over the years, research has fleshed out a deeper understanding of the Acheulean complex across the African continent.

Although Leakey preferred the term *biface* to the functionally defined types of cleaver and handaxe, the best generic term today for these diagnostic types is the large cutting tool (LCT). This term is preferable because handaxes are not always bifacial and also because picks (which are sometimes trihedral) were not usually discussed as bifaces. Many LCTs are made on large flakes because such blanks are relatively thinner, with accessible edges, making it easier to shape the piece, but cobbles were also used for handaxes in some assemblages and very occasionally for cleavers. At some sites, there are preferences of particular raw materials for LCTs, such as large lava or quartzite cobbles and boulders, because they yield large flakes of better size and quality. Overall, the technology of many of the earliest Acheulean assemblages is relatively similar to the classic Oldowan or only slightly more advanced in core working strategies, with large flakes and LCTs largely an added component. However, there are some clear behavioral changes apparent in the size and distribution of sites from 1.7 Ma. A trend toward larger sites and greater densities of stone tools within a site reflects a more habitual dependence on lithics for daily subsistence, and there is a more sustained use of some venues as strategic locations or for seasonal resources. Sites also occur in a greater variety of environments and include the more consistent use of open habitats. Occasionally, some raw materials are transported further distances than is typical in the preceding Oldowan, reflecting the broader use of landscapes.

The controlled use of fire was a further innovation in the earlier Acheulean, especially as it provided a means of defense against carnivores in open habitats where hominids competed for game. However, the interpretation of early campfires is controversial due to poor preservation in open-air sites. A few East African sites c. 1.5 Ma contain burnt sediments accepted by many researchers as plausible evidence of campfires, as heat of a certain temperature must be sustained long enough to alter the ground. There is also patterning at some sites in the spatial distribution of lithics and bone around these burnt features, which strengthens the argument for the controlled use of fire in the Early Acheulean. However, in South Africa by 1 Ma, there is evidence for bones burnt in campfires at the surface and washed into an underground cave deposit at Swartkrans (Brain 2004). Also c. 1 Ma at Wonderwerk Cave, ashed plant remains, and fragments of burnt bone are documented within an Acheulean occupation layer about 30 m from the modern cave entrance (Berna et al. 2012). By c. 0.79 Ma, the open-air site of Gesher Benot Ya'aqov in Israel has burnt artifacts and charred botanical remains with a patterned distribution that suggests activities associated with hearths (Goren-Inbar et al. 2018).

Key Issues/Current Debates

The Earliest Acheulean

The appearance of a new African hominid, *Homo ergaster* (Fig. 1), is the most plausible explanation for the behavioral and technological changes that appear with the Acheulean. This species has more sapient-like traits than *Homo habilis*, including modern human body proportions which provided an advantage in open habitats. Many researchers group *H. ergaster* with *Homo erectus* or refer to it as African *Homo erectus*, while others restrict the

Acheulean Industrial Complex, Fig. 1 The earliest Acheulean is contemporary with a new hominid species, *Homo ergaster*, considered to be responsible for cultural innovations. KNM-ER 3733 from Kenya (*far left*) is the most complete cranial specimen and is shown facing SK 847 (*center*) from Swartkrans, which was the first discovery of this species. At right is the type specimen, the KNM-ER 992 mandible from Kenya, shown together with 3733. They are not the same individual. (All photos are of casts, courtesy of R. J. Clarke)

erectus species to Asia, which is the classification followed here. The earliest appearance of *H. ergaster* is dated to 1.78 Ma in Kenya (Lepre and Kent 2010) and to >1.7 Ma at Swartkrans in South Africa (Pickering et al. 2012). At Sterkfontein in South Africa, it is found in direct association with Early Acheulean artifacts (Kuman and Clarke 2000). The species persists until at least 1.4 Ma, and thus there is a good match with Early Acheulean chronology.

Many of the historically important debates concerning the Early Acheulean are today increasingly less relevant. For example, Leakey's (1971) classification system regarded many core-based forms as tools rather than cores, considering the sharp edges created by platform intersections to be working edges. She then used a quantitative analysis of these types (which included the "bifaces") to arrive at her formal definition for the Acheulean industry: an assemblage in which 40% or more of the "tools" consist of bifaces. Assemblages which did not meet this criterion were designated as Developed Oldowan. However, few researchers today use this term as the technical differences once considered important have other, better explanations. Today the range of variability in the Early Acheulean is clearer, and technological and behavioral traits that reflect the increasing complexity of the adaptation allow researchers to recognize such assemblages even when LCTs are absent due to activity differences or small sample sizes.

Kokiselei (West Lake Turkana, Kenya) is the earliest dated Acheulean site at 1.76 Ma (Lepre et al. 2011). Other dates for major East African sites are 1.7–1.4 Ma at Konso, Ethiopia; 1.7–1.4 at Gona, Ethiopia; 1.7–1.4 Ma at Olduvai, Tanzania; and c. 1.5–1.4 Ma at East Lake Turkana, Kenya (see de la Torre 2016). In South Africa, equally Early Acheulean assemblages are well established but less well-dated in the karst hominid sites of Sterkfontein and Swartkrans (Kuman 2007; Kuman and Clarke 2000), which have infills in underground contexts deposited from surface occupations. Faunal ages for cave breccias with Early Acheulean are c. 1.5 Ma and 1 Ma at Swartkrans and c. 1.6 Ma at Sterkfontein. While there have been claims for younger ages at Sterkfontein in a number of deposits, the dating methods employed have their own problems at these karst sites. Paleomagnetic and U-Pb dates for Sterkfontein have been argued based on speleothems, but these have formed post-depositionally after the collapse and settling of breccias created voids that later filled with flowstone. Also problematic are younger electronic spin resonance dates proposed for the Sterkfontein breccias, as the migration of groundwater through deposits compromises the closed system needed for ESR dating. Typologically and technologically, the

Sterkfontein LCTs are comparable to Early Acheulean examples from East Africa, and attempts to obtain cosmogenic dates are in progress. In interior South Africa, cosmogenic dating has documented Early Acheulean artifacts in alluvial deposits of the Vaal River basin (Fig. 2), with dated deposits ranging from 1.7 to 1.3 Ma (Gibbon et al. 2009; Kuman and Gibbon 2018; see Leader et al. 2018 for revised dating). Due to the limitations of geological preservation and dating in East and South Africa, the Early Acheulean industries in these two regions provide our best evidence for the widespread distribution in Africa of this complex by 1.7 Ma.

Descriptions of Early Acheulean technology and tool types have largely focused on the shaping of LCTs (Fig. 3), as more effort tends to be invested

Acheulean Industrial Complex, Fig. 2 Early Acheulean LCTs from Rietputs 15, South Africa, where sites have been dated from 1.7 to 1.3 Ma. Handaxes (**a**, **b**) and a cleaver (**c**) on flakes; handaxes (**d**, **e**) and picks (**f**, **g**) on cobbles (From Gibbon et al. 2009)

Acheulean Industrial Complex, Fig. 3 Early Acheulean LCTs of East and South Africa are comparable. *Right* are from Mary Leakey's type series from EF-HR, Olduvai Gorge; *left* are from Member 5, Sterkfontein

Acheulean Industrial Complex, Fig. 4 Broken handaxes and handaxe tips from BK, Olduvai, most probably resulting from flaking to re-sharpen the pieces

in such tools. LCTs from Konso and Kokiselei have been described as large pick-like pieces or "pick-like handaxes." The heavy-duty function of these tools may have been for digging underground foods such as bulbs, roots, and tubers. However, such types do not dominate in all the early assemblages. Handaxes from EF-HR at Olduvai and Peninj in Tanzania have been described as largely unifacial pieces – like massive scrapers with robust convergent tips (De la Torre et al. 2008). The notched edges on some examples from Peninj, EF-HR, and Sterkfontein suggest woodworking was another important function. In some assemblages, pick-like handaxes and unifacial handaxes with robust tips and scraper edges are only a minor component of the LCTs, but early handaxes generally all possess strong distals converging to a more or less flat tip for some hacking or cutting function. The degree of trimming to shape a handaxe also ranges from largely unifacial to partly bifacial to fully bifacial. However, many assemblages tend to be dominated by one type of shaping within this range, which is often determined by the degree of re-sharpening. For example, the BK assemblage from Olduvai (Fig. 4) includes some classic bifacial handaxes, along with likely evidence for re-sharpening in the form of distals broken through end-shock during knapping, as well as some very small-sized bifaces. Although some early assemblages are dominated by pick-like handaxes, many researchers are able to distinguish picks as a separate type: an LCT in which the shaping is focused mostly on the distal end, with limited attention given to the body of the piece. Following the Early Acheulean, however, picks and handaxes are easier to separate as discrete types.

Another very characteristic type in the African Early Acheulean is the cleaver – an LCT made usually on a large flake, with a broad cutting edge at the distal end and/or along one lateral. The cutting edge is referred to as the "bit." It is usually formed by the naturally sharp portion of the large flake blank, but rare examples of bits shaped by removals do occur in the early assemblages, presumably to regularize the shape of the cutting edge. The making of a cleaver requires some planning for the large flake to be detached in order to produce a sizeable bit. The most classic cleaver type for both the early and younger Acheulean industries is one made on a large side-struck flake – a flake that is wider than it is long, with the bulb at the side of the flake's long axis. The thick platform area is then trimmed with some large removals, and the opposite lateral may also be trimmed (particularly in younger Acheulean assemblages). However, examples of cleavers on corner-struck and end-struck flakes also commonly occur. The cleaver bit implies that the tool was used for a cutting or hacking function requiring a sizeable sharp edge and a tool with weight. Experiments suggest that cleavers make good dismembering tools in butchery, but handaxes and plain flakes can also perform this function. A small number of pieces studied for use-wear traces, micropolish, or phytoliths also suggest that some cleavers may have been used for chopping and scraping wood.

The raw material and the blank's form have a strong influence on the regularity of shape for LCTs, and the Early Acheulean is characterized by both crude and relatively finer examples when made in better raw materials. However, it is essential to remember that LCTs were functional pieces and there was no need for early *Homo* to produce standardized forms, symmetrical handaxes, or elegant shapes. The iconic concept of the classic, symmetrically shaped handaxe or elegant cleaver, when it occurs, is most often found in Later Acheulean assemblages after 0.6 Ma (discussed below). However, it is during the earlier Acheulean that the first handaxe industries appeared beyond the African continent. Ubeidiya in Israel has a sequence of Early Acheulean deposits from 1.4 Ma, and the Early Acheulean has also been documented in India c. 1.5 Ma with cosmogenic burial dating. The earliest handaxes in China appear by at least 0.8 Ma (at Yunxian in central China and Bose in southwestern China). In Europe, the earliest Acheulean may be as old as ca 1.0 Ma in Spain, but it only becomes widespread after 0.5 Ma.

From 1 to 0.6 Ma: Developments Following the Early Acheulean

While sites dated between 1.7 and 1.4/1.3 Ma are consistently referred to as Early Acheulean in the literature, there is no consensus on terminology for the following phases of ESA development. This is certainly a result of the limited number of sites and especially dates for the period between 1.3 and 0.78 Ma. Terms such as Early, Middle, and Later Acheulean are also historical labels created at a time when few absolute dates were available. Consequently, some researchers prefer to lump Acheulean sites into only two phases: Lower and Upper Acheulean or Early and Later Acheulean. However, with today's better understanding of Acheulean developments c. 1 Ma, there is some justification to recognize a Middle Acheulean phase from approximately 1.0 to 0.6 Ma. East African sites at this time demonstrate improvements in LCT production, as outlined below, and some sites show increased numbers of handaxes. Changes in handaxe flaking are probably the result of more attention paid to creating sharp cutting edges, and picks are now easier to separate into a class of their own.

At Olduvai, the sequence following the Early Acheulean in middle and upper Bed II has been published in some detail (Leakey and Roe 1994). Although the preservation of these younger assemblages is poor relative to the Early Acheulean and dating of these beds is not so precise, Roe was able to characterize changes in technology following the Early Acheulean: the Bed IV handaxes (c. 0.95–0.78 Ma – Peters et al. 2008) show more regularity of shapes and thinner profiles over the Early Acheulean, and cleavers become more frequent and often more elegantly made. Advances in the shaping and thinness of the Bed IV LCTs have since been demonstrated quantitatively by Shipton (2018), and these

improvements support the notion of a Middle Acheulean technology. Following Bed IV are the Masek Beds (c. 0.78–0.5 Ma – Peters et al. 2008), in which handaxe manufacture shows even greater standardization of preferred shapes and a high degree of technological competence. In Kenya, Olorgesailie also has a lengthy sequence, now known to date from 1.2 to 0.5 Ma. Before such ages were achieved, Isaac (1977: 213) classified the site as Upper Acheulean because "reliable chronological distinctions… are not possible." However, he commented that the assemblages are not the most refined and that one might be tempted to designate them as Middle Acheulean. Similar improvements over time are also recorded for the long sequence of Acheulean sites in the Middle Awash of Ethiopia (de Heinzelin et al. 2000). Soft-hammer flaking made its first appearance in the Middle Acheulean, with the earliest date for this technique reported from Gesher Benot Ya'aqov, Israel, at c. 0.79 Ma (Goren-Inbar et al. 2018). Potential soft percussors could have been a softer stone (like sandstone), a hardwood billet, or in Eurasia deer antler. The method is useful for detaching thinner flakes that extend further across the surface of an LCT and for finer retouching along the edges. However, the technique is more typically seen used for LCTs in the Later Acheulean.

A handful of hominid fossils is found with industries that could be termed Middle Acheulean. Several specimens from Daka, Ethiopia, are dated to 1 Ma, including a remarkable cranium described as an evolving form of *Homo ergaster* (de Heinzelin et al. 2000). The illustrated LCTs show better technique and are more regular in form than Early Acheulean examples, but overall they are described as having bold flake scars and are larger and more irregular in plan view and profile than Later Acheulean examples. Also dating to 1 Ma is Buia in Eritrea which yielded a hominid cranium that, like Daka, possesses some progressive features. LCTs show variability across the Buia sites but are comparable in many respects to those of Daka, with bold scars and limited trimming that does not significantly modify the original blank's morphology (Abbate et al. 2004). Olorgesailie in Kenya has also yielded fragments of a hominid cranium at least 0.9 Ma, contemporary with Middle Acheulean elsewhere at the site. For South Africa, little detail is currently available for hominids in this time range as few dates are available for potential sites. An exception is Uitzhoek-Cornelia, but so far this site has only yielded one hominid tooth (Brink et al. 2012).

Most research on Acheulean sites today is focused on documenting the cultural and stratigraphic record of the relevant sites and obtaining reliable dates and paleoenvironmental information. From a theoretical perspective, however, the "variability selection hypothesis" for hominid and cultural evolution has received widespread acceptance (Potts 1998). It argues that the driving force behind human evolution in the Pleistocene has been climatic change and the periodic fluctuations between moister and wetter environments over hundreds of thousands of years. *Homo* rose to this challenge of variability in climate and subsistence resources and adapted both physically and culturally. Fauna has long been the primary means of reconstructing paleoenvironments when it is preserved. Isotopic studies (particularly on faunal teeth) are now a major means of analyzing diets, and hence the habitats of hominids and fauna, supplementing data that was previously limited to lists of taxa and their correlation with modern habitats. As the diets of some modern species differ somewhat relative to their past counterparts, isotopic analysis has become a valuable tool to discover those differences. Some researchers also focus on "taxon-free" analysis, studying the details of weight-bearing postcranial bones in relation to habitat substrates, particularly in bovids. And dental microwear analysis has shed further light on subsistence patterns of both fauna and hominids and hence habitat adaptations. Analysis of plant phytoliths and pollen, when preserved, along with stable carbon isotopes from sediments and geomorphological reconstruction, is another means of studying past environments. The varied regional habitats that existed across Africa during the Pleistocene add strength to the hypothesis of fluctuating climates as a driving force in hominid evolution.

Another area of focus in Middle Pleistocene research is the origins of prepared core technology

within the Acheulean. The earliest published date for this development is in Israel c. 0.79 Ma (Goren-Inbar et al. 2018). However, a cosmogenic burial date for the Victoria West industry from Canteen Kopje, South Africa (still to be published), is older, and although the prepared cores are not the most common, they are substantial in number. These two unrelated examples suggest that the ancestor of *Homo sapiens* had relatively sophisticated cognitive abilities which were, so to speak, "hardwired" in the brain. Many researchers believe that the shaping of handaxes gave rise to the concept of core preparation, and the Victoria West industry demonstrates this well (Figs. 5 and 6). These almond-shaped cores are flaked initially like a very large handaxe with bold scars. However, the profile is more asymmetrical, with a shallower upper surface and a deeper lower surface. A single large "preferential" flake is struck from the upper surface, perpendicular to the long axis of the core. Such side-struck flakes were particularly suitable blanks for LCT manufacture. Although the Victoria West core is a small component of the overall cores in excavated samples, it clearly shows the conceptual link with handaxe manufacture. "Giant cores" are also present at Gesher Benot Ya'aqov and appear to have been specially targeted for the making of LCT blanks. Hominid size and strength at this time must have enhanced human survival considerably, and this is reflected in the giant cores and the heavy-duty tools.

Acheulean Industrial Complex, Fig. 6 Victoria West prepared core technology. At *left* are two prepared cores in profile view, showing the deeper undersurface and flatter upper surface used for the large flake removal. At *right* an LCT made on a large prepared flake is shown over the large flake scar on the upper core surface

From 0.6 Ma to 0.3–2 Ma: The Later Acheulean and Final ESA

From 0.6 Ma, the number of archaeological sites in Africa increases (Clark 2001a), not merely because younger sites are more likely to be preserved but because of the successful adaptations of evolving *Homo sapiens*. In particular, a slower rate of maturation for early *Homo sapiens* undoubtedly influenced the success of the species at this time. In contrast, even *Homo ergaster* matured relatively quickly. The specific age of an early *Homo* fossil may be difficult to know for certain, but it is today well documented that the rate at which an early *Homo ergaster* juvenile reached maturity was faster than in modern humans, and this fact undoubtedly influenced the character of earlier Acheulean industries. Hominids learned to make tools by observing and learning their group's tradition, but a shorter adolescence would have limited the time for individuals to experiment and innovate. Studies of nonhuman primates show that it is mainly the younger individuals who invent new cultural practices or adopt innovations from others in the group through observation.

While most variability in the Later Acheulean from c. 0.6 to 0.3 Ma can be explained by differences in raw materials and environment (Clark 2001a), there is nevertheless greater skill evident in the flaking of cores, in the acquisition of some better raw materials from distant sources, and in the shaping of the best LCT examples. The most logical explanation for these changes is not the appearance of a dramatically different, more advanced hominid but the increase of more sapient traits and cognitive abilities in the descendants of *H. ergaster*. Some researchers lump the hominids of this phase together as *Homo heidelbergensis*, but many specialists prefer to restrict this species to Europe and refer the fossils to early *Homo sapiens*. The relevant fossils are all associated with the Later Acheulean period and include the Bodo cranium from Ethiopia c. 0.6 Ma, the Elandsfontein skullcap from South Africa c. 0.6 Ma, and the Ndutu cranium from Tanzania >0.4 Ma. The Kabwe cranium (initially called Rhodesian Man or *Homo rhodesiensis*) was retrieved by miners at Broken Hill, Zambia. It is undated but similar to the Elandsfontein hominid. Middle Stone Age artifacts were also found in the cave deposits but in unknown relationship, while Acheulean and Sangoan assemblages (discussed later) were excavated in open-air deposits not far from the cave.

Although Wonderwerk Cave is argued on microstratigraphy to show occupations much earlier for both the Oldowan and earlier Acheulean levels, early humans only occupied caves more consistently during the Later Acheulean (e.g., at Cave of Hearths, Montagu Cave, and Wonderwerk in South Africa). For the earlier levels at Wonderwerk, it is likely that hominids sheltered or slept in the cave at times, as some rare baboon and chimpanzee troops have been recorded to do, and this could explain the smaller numbers of tools in these levels, as well as the signs of fire c. 1 Ma (see further reading suggestions).

Open-air sites of the Later Acheulean in Africa are much more numerous, although many remain poorly dated. Some of the most detailed descriptions of Later Acheulean industries are published for Olduvai, Tanzania (Leakey and Roe 1994), the Middle Awash Valley of Ethiopia (de Heinzelin et al. 2000), and Cave of Hearths in South Africa (see further reading: McNabb and Sinclair 2009). All Later Acheulean assemblages show considerable improvement in skill over earlier phases, even though there is very often a "least effort" approach, with just enough flaking to get the desired edge. The sequence at Kalambo Falls deserves special comment, as it is well described and includes both Later Acheulean and an overlying final ESA industry known as Sangoan (Clark 2001b). Experienced knappers have commented that the Kalambo LCTs show some of the finest proficiency in the African Acheulean, with refined technique evident in sharp cutting edges around all or most of the perimeter, intensive flaking, absence of step fractures, symmetrical plan forms and cross sections, careful removal of small flakes as a last series of removals to regularize edges, and use of soft-hammer flaking for the finer work (Clark 2001b, Chap. 11). Not all Later Acheulean LCTs are beautifully made, but when effort is invested in a good raw material or the maker is highly experienced, there is great skill evident, demonstrating what Glynn Isaac

Acheulean Industrial Complex, Fig. 7 Some of the more finely worked handaxes from the Later Acheulean at Cave of Hearths, South Africa, showing extensive flaking

referred to as the "upper limits" of the abilities manifested in an industry (Fig. 7).

The significance of blades in the Later Acheulean and the transition to the Middle Stone Age (MSA) are often noted, as blades require a purposeful flaking strategy to be made with any consistency. Three of the oldest regional industries with blades date back to c. 0.5–0.4 Ma (see Wilkins and Chazan 2012 for references). Along with blades, the Fauresmith industry at Kathu Pan and other South African Fauresmith sites (c. 0.5–0.29 Ma) include some LCTs, points, and prepared cores. Similarly, the Kapthurin industry in Kenya has core preparation and blades from c. 0.55 to 0.285 Ma. In Israel, a third blade technology is the Amudian, c. 0.42–0.32 Ma. These three technologies are unrelated as the techniques differ. In Africa, Acheulean blade tools tend to be associated with more open habitats (Clark 2001a). Another trait noted occasionally in some late assemblages is small-sized LCTs, some of which overlap in length with the larger early MSA points and unifaces. The most variable and skilled assemblages of the Later Acheulean occur in the late or final phase of the Acheulean, with retouched tools and technology presaging MSA features in some industries (Clark 2001a). Due to such similarities, many researchers recognize regional transitions from ESA to MSA but will label an assemblage Acheulean if it contains LCTs. However, the Kapthurin and Fauresmith industries both suggest a reduction in numbers of handaxes and a slow transition toward MSA technology in different parts of Africa.

Clark (2001a) always maintained that the late ESA was the first time that hominids coped with the challenges of more forested environments. The Sangoan was named as a central African industry found in regions that today are tropical. While the original collections were retrieved from disturbed geological contexts, subsequent research has documented the Sangoan in context, where it follows the Acheulean in time in sites where both phases are present as distinct industries. It is found mainly in central and south central Africa and western Kenya where woodlands were prominent at times. At Kalambo Falls, climates alternated between warmer/moister and colder/drier episodes, indicating that the Sangoan was not specifically a tropical or closed habitat adaptation. Rather it occurred in regions where woodland resources were an important component. Typical tools include small scrapers, picks,

and core axes, a type which seems to have functioned as a form of adze for woodworking and cutting toeholds for climbing in trees (Clark 2001b). Acheulean-style handaxes continue to occur in small numbers, and thus some researchers see the Sangoan industry as a variant of the Later Acheulean with the addition of some new types related to the prominence of woodland resources. In Zambia and western Kenya, there are some shared features between Sangoan and early MSA industries, such as the core axes at Kalambo Falls which continue in the early MSA but become increasingly adze-like. In western Kenya, the Sangoan and the Lupemban (an early MSA industry) share so many traits that at least one researcher refers to the Sangoan-Lupemban Complex. Precise dates are not available for Sangoan industries, but they are at least 0.1–0.2 Ma, and some may be considerably older.

International Perspectives

The most interesting theoretical aspect of Acheulean research is perhaps the "variable sameness" of the industries across time and space in Africa and Eurasia until the Later Acheulean. Even then, most variability is attributed to raw material differences, and one is left with an impression that the toolmakers were very clever people indeed, but still relatively archaic in mind and matter when compared to modern humans that appeared by 0.3 Ma with the early MSA. Industries then become considerably more variable, with many regional adaptations that include some stylistic differences, and the pace of change picks up even more during the course of the MSA. Various researchers have debated the meaning of Acheulean variability and the methods used to analyze it both regionally and globally. However, the most informative approach remains a thorough understanding of Acheulean assemblages in the context of experimental flaking with the specific raw materials that influenced their characters. Such hands-on experience always provides valuable insights, often more informative than detailed morphometric and statistical studies used today, as they help to interpret factors related to tool-making and tool functions. The Acheulean was undoubtedly a highly successful adaptation from 1.7 to 0.3–0.2 Ma ago, with an emphasis on open woodland and grassland subsistence until the appearance of the Sangoan variant. The final ESA, however, is unique, witnessing the transition from early *H. sapiens* to modern humans. The success of the Early Acheulean and *Homo ergaster* as a species clearly set the stage for these milestones in human development.

Activism and Archaeology

Larry J. Zimmerman
Indiana University-Purdue University Indianapolis/Eiteljorg Museum, Indianapolis, IN, USA

Introduction

For most people, including many archaeologists, archaeology is about the more distant past.

Archaeology is more interesting and esoteric than actually being useful. After all, the "archaeo" part of the word means "ancient"! Thus, the past is over and done with, and while it may be intrinsically interesting or provide us with perspective on our lives and cultural changes through time, the past does not seem to be of much use in dealing with contemporary issues. Other archaeologists, however, have called on archaeology to become more action oriented and for archaeologists to explore more ways to use archaeology to address contemporary problems (Kleindienst and Watson 1956). They want archaeology to matter (Sabloff 2008) arguing that archaeologists "...have responsibilities towards the communities, individuals, and institutions directly implicated by archaeological work into the recent past in helping them come to terms with the obscured and often painful circumstances of contemporary life" (Buchli 2007: 14). To do this, archaeologists must first acknowledge that the past actually includes anything from the briefest moment ago into the depths of time (Patel 2007: 51).

Archaeology is really more about the study of material culture than about the past and can be applied to *any* period of time. Expressed simply, artifacts do not "lie"; they are present or they are not, which in either case may require explanation. Although archaeologists may err in their interpretations, their goal is to recover material remnants of past behaviors and their contexts in order to provide a narrative – a story – about the history of a people, their lifeways, their adaptations to changes in natural and social environment, and what things mean to them. This can be a powerful way of seeing the past, which makes archaeology potentially useful in understanding contemporary concerns. Archaeology's applicability to the present stems from three key elements: studying material culture, building accurate narratives about the past based on what is found, and using the narratives to suggest changes relating to social concerns. To realize this potential, however, requires activism.

Definition

Activism generally is the use of some kind of direct action either in support of or in opposition to a cause or issue. When linked to archaeology, this means that the tools of archaeology are applied in some way to support or oppose an issue in an effort to promote change. Activism requires that archaeologists make choices and then take some sort of political position, usually in collaboration with stakeholders to that issue, in an effort to effect the desired change.

Activism depends heavily on collaboration with non-archaeologists. Projects are sometimes low key exercises in public education about what archaeology does or uses archaeology to address relatively uncomplicated concerns. Several projects, for example, employ archaeology to demonstrate the historical basis and impacts of race in a community, and others use particular archaeological techniques to assist with mass disasters. On the other end of the continuum are projects in which archaeology is only one aspect of studying very complex social problems such as homelessness or global warming. Little and Zimmerman (2010) and Stottman (2010) provide numerous examples spanning the spectrum of activist archaeology projects.

Key Issues/Current Debates/Future Directions/Examples

Two key issues impede activism. The first is that activism requires archaeologists to be political, which many have been loath to do. The second is that even if they are willing to be activists, few archaeologists know how to translate the results of their work in ways useful to the formulation of public policy.

The former stems from archaeology's long struggle to become scientific, and as such, many archaeologists believe that archaeologists and their interpretations must be objective and unbiased. Some altogether reject studies of the contemporary past as even being archaeology, suggesting that they epistemologically reflect postmodernism. As a few activist archaeologists

have heard from colleagues, "you do politics, not archaeology!" In spite of the fact that there is disagreement with his assessments, McGuire (2008) has contended, however, that archaeology always has been and still is clearly political.

Accepting archaeology as inherently political, a growing number of archaeologists have moved toward making their research "translational". This means that they "generate knowledge and utilize evidence to develop meaningful practices that address problems or issues in everyday life and collaborate or form partnerships to successfully translate evidence into meaningful practices" in order to make a difference in people's lives (Zimmerman et al. 2010: 444–45). In other words, by working with others, they find ways to put archaeology to use. Doing so is not always easy and carries risks of alienating collaborators or other powerful stakeholders. Given the limited experience of most archaeologists with activism, most are relying on a case-by-case approach to projects and use a lot of experimentation. To say that the discipline has yet to develop an encompassing epistemology for activism and is nowhere close to a set of "best practices" would be a profound understatement.

Actor Network Theory (ANT)

Kelly D. Wiltshire
Department of Archaeology, College of Humanities Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

Actor-Network Theory (ANT) is a framework for the study of sociology that emerged in the early 1980s with the work of Bruno Latour, Michel Callon, and John Law in the field of Science and Technology Studies (STS). Bruno Latour continued to develop ANT throughout the 1990s, where its application moved beyond the boundaries of STS and made its way into other disciplines outside sociology. The application of ANT within the archaeological discipline has predominantly occurred through the development of symmetrical archaeology, which seeks to apply the ANT concept of symmetry in order to develop more complex interpretations within the archaeological discipline. Beyond this, the application of ANT

by archaeologists exists within a number of isolated case studies in the subfields of maritime archaeology aviation archaeology, and ethnographies of archaeological practice.

Definition

ANT primarily emerged as a result of sociologies of scientific practice that developed in the early 1980s within the field of STS. These studies use participant observation to produce detailed ethnographic descriptions of scientific "data" and "fact" production, concluding scientific knowledge to be a socially constructed product of both laboratory cultural practices and the social connections that exist between scientists (Harman 2007:43). Despite being an early proponent in the social construction of scientific knowledge, sociologist and philosopher Bruno Latour was also the first to abandon social construction, claiming it to be the key weakness of early sociologies of science (Van Rebrouck and Jacobs 2006:36–37). Specifically, Latour (2005:7) argues there is an assumption within traditional sociology that the social is a distinct micro-context of reality separate from economic and/or political contexts. Latour maintains the entire notion of contexts, particularly social contexts, creates an unnecessary dichotomy that restricts ethnographic descriptions of knowledge production to social contexts and socially derived outcomes. In response to this, Latour took inspiration from French philosophers Giles Deleuze and Félix Guattari's (1980) assemblage theory in order to reconceptualize or "reassemble" (cf. Latour 2005) the nature of social contexts. In doing so, Latour (1999, 2005) developed ANT as an inductive method of ethnographic description to describe the production of knowledge outside a given context.

Despite the inclusion of the word "theory," ANT is a *method* of inquiry rather than a theory (Latour 1999:19). As John Law (2009:142) argues, "it is a toolkit for telling interesting stories. . .about how relations assemble." In other words, ANT is used as a method to describe the relationships or connections that comprise a particular network or assemblage; however, to fully comprehend ANT as a method, it needs to be described in relation to the specific case study in which it is being applied (see Latour 2005:141–156). In spite of this, ANT does emphasize the use of key concepts including symmetry, translation, and black boxing. These key concepts have been adopted by proponents of symmetrical archaeology and/or applied within a number isolated case studies in the subfields of maritime archaeology, aviation archaeology, and ethnographies of archaeological practice.

Key Issues/Current Debates/Future Directions/Examples

Within the archaeological discipline, the most predominant application of ANT has occurred through the development of symmetrical archaeology, which applies the ANT concept of symmetry in order to draw attention to the often marginalized or silenced agency of nonhumans. Latour (1999:190) argues the agency of nonhumans has resided in a "blind spot" in society, with their agency ignored socially, politically, and philosophically despite the fact humans depend on and care for nonhumans in our everyday lives; however, ANT maintains nonhumans are not passive, inert, or inanimate but are actors with the capacity to act alongside human actors (Harman 2007; Hodder 2012; Olsen et al. 2012). Thus, the concept of symmetry seeks to promote the equal agency of human and nonhuman actors in order to create a "flat ontology," which treats all humans and nonhumans democratically.

In applying this concept, symmetrical archaeology argues the archaeological discipline produces anthropocentric histories that emphasize the "Indian [sic] behind the artefact" (Braidwood 1958:734) but has failed to recognize the agency of nonhumans or things. In essence, things have been forgotten. For example, key practitioner of symmetrical archaeology Bjørnar Olsen (2007:580; 582) believes the archaeological discipline and the histories it produces have kept things at arm's length:

> (what) we see is basically a prolonged asymmetry, in which things continue to be treated as secondary or epiphenomenal to some cultural or social 'first

> instance'. . .[where] the material inhabitants were plastic and receptive, sitting in silence waiting to be embodied with cultural significance.

Alternatively, symmetrical archaeology can offer a distinct and reconceptualized focus on things, where the metaphor of an assemblage or network is used to better understand the agency of things. For example, things make a difference, not just because of their agency and ability act but because of the reciprocal mutually constitutive connection that exists between human and nonhuman actors as part of an assemblage or network (Latour 2005). In other words, agency is possessed in connections between actors rather than in actors themselves, with agency relative to and distributed via the assemblage within which they are situated (Lucas 2012:162). Therefore, proponents of symmetrical archaeology argue being sensitive to the connections that exist between humans and nonhumans can result in far more complex archaeological interpretations (Olsen et al. 2012:14).

Ian Hodder's (2012) *Entangled: An Archaeology of the Relationships Between Humans and Things* also draws upon the metaphor of an assemblage to explore the spatial and temporal relationships between humans and nonhumans. In doing so, Hodder (2012:91–94) initially explores the concept of ANT but soon rejects it on the basis of its symmetry and instead favors the concept of entanglement to convey the dependence that exists between human and nonhumans. Consequently, the concept symmetry and the creation of a "flat ontology" are the key criticisms of ANT. Critics claim this democratic approach does not account for or challenge pre-existing systems of asymmetrical power and authority or inequality (Amsterdamska 1990; Restivo 2005; Whittle and Spicer 2008). Utilizing ANT has the potential to obscure systems that marginalize particular groups or individuals, or their agency, in resisting this marginalization. Despite this, ANT understands hegemonic systems of power and authority as a product or effect of pre-existing assemblages and not a predetermined reality (Latour 2005:64). Therefore, despite not recognizing or challenging pre-existing hegemonic systems of power and authority, ANT can be used to describe the assemblages that create and maintain such systems, which becomes a useful tool in challenging such structures.

Beyond the development of symmetrical archaeology, the application of ANT by archaeologists has existed within a few case studies. In an early example, Whitridge (2004) considers the complex technical assemblage that resulted in stylistic variability in harpoon heads observed archaeologically, which in turn contributed to changes in whaling practices in the North American Artic around 1000 AD. In doing so, Whitridge's (2004) example is one of the few that demonstrates how ANT can be applied to develop more complex archaeological interpretations. Accordingly, many of the other archaeological case studies that exist under the ANT umbrella seek to describe the archaeological practice and/or the production of knowledge, aligning these case studies with the field of sociologies of scientific practice from which ANT emerged. In another early example, Jones' (2002) *Archaeological Theory and Scientific Practice* explicitly draws upon STS and ANT in his analysis of archaeological practice, arguing research questions, hypotheses, techniques, sampling strategies, and scales limit the production of archaeological knowledges. In addition to this, Jones draws upon the ANT concept of symmetry to explore the agency of archaeological traces in influencing the production of archaeological knowledge. Both Yarrow (2003) and Van Rebrouck and Jacobs (2006) apply the ANT concept of symmetry to explore the mutually constitutive nature of the connection between subject and object or archaeologists and archaeology that plays out during archaeological excavation, demonstrating neither archaeologist nor archaeology is self-evident but emerges simultaneously as a result of the connection that develops during archaeological practice. In other words, without the archaeology there can be no archaeologist. More recently, Deal et al. (2015) apply ANT to explore the social and technical actors that comprise and produce knowledge within the emerging field of aviation archaeology, whereas Van

Oyen (2015) explores how archaeological understandings of Roman pottery types became a constructed yet an imbedded form of categorization.

Lastly, research by Wiltshire (2017) uses ANT to reconceptualize archaeological practice as an assemblage, in order to describe the heterogeneous actors often marginalized in the production of archaeological knowledges. In doing so, this research moves beyond the ANT concept of symmetry, to include the concept of translation in order to identify and describe how connections between actors assemble, shift, and fell apart over the course of archaeological investigations. Specifically, the concept of translation is a process where one actor transforms another through connections that involve work, negotiation, and resistance between actors (Harman 2007:40–41). When translation has succeeded, one actor has worked upon another to translate it to become part of an assemblage (Latour 1999). Alternatively, when actors are not transformed by other actors, they do not form part of an assemblage. As a result of this process of translation, assemblages are continually being made, remade, shaped, and reshaped and are constantly shifting through the dynamic connections that exist between actors. In other words, assemblages are not static or permanent but are dynamic, and ANT allows for the study of numerous moments of translation by describing how the connections between actors assemble, shift, and fall apart (Latour 2005:132). For Wiltshire (2017), this concept is used to highlight how the agency of the Ngarrindjeri Nation resulted in a process of translation, ultimately influencing the development of the researcher's role as an archaeologist. In addition to this, successful and unsuccessful instances of translation are also described. Specifically, this research describes how the connection between the Ngarrindjeri Nation and the researcher allowed for the initiation of archaeological investigations, while the nature of this connection including the agency of gender contributed to the conclusion of archaeological investigations.

Following on from the concept of translation, Wiltshire (2017) also applies the concept of black boxing to identify and describe how successful and unsuccessful instances of translation became concealed. Once successful translation occurs, an assemblage appears static, stable, and self-evident, which conceals the heterogeneous actors that comprise it, and focus is directed toward one or few actants (Latour 1999). For example, the discovery of archaeological facts is attributed to the authoritative archaeologist, while other human and nonhuman actors that are part of the assemblage of archaeological practice and contribute to the production of these facts are marginalized and silenced.

Black boxing also allows for particular knowledges and/or practices to become accepted, rather than allowing them to be continually critiqued, refined, and reproduced to reflect the dynamic nature of the assemblage that produced them. In describing the concept of black boxing in relation to archaeological practice, Leighton (2015:68) explains:

> Black-boxing refers to the extent to which a scientific knowledge claim needs to be justified and explained within a specific scientific community. For instance, when radiocarbon dating was a new technology, its use was a matter of uncertainty and debate, but today an author writing in an archaeological journal does not need to explicitly convince his or her readers that C14 is an appropriate way to date an archaeological layer. Archaeologists no longer have to explain, justify and prove the concept of radioactive decay every time they want to make use of a C14 date in a paper, and in this sense C14 dating has become a black-boxed 'matter of fact' rather than an open problem one needs to think about, pay attention to and justify explicitly.

In applying the concept of black boxing, Wiltshire (2017) describes how successful and unsuccessful instances of translation became concealed, particularly during the production of written texts and reports that obscure emotion actors such as uncertainty and excitement.

Adandé, Alexis B. A.

Didier N'Dah
Département d'Histoire et d'Archéologie,
Université d'Abomey-Calavi, Abomey-Calavi,
République du Bénin

Basic Biographical Information

Dr. Alexis Bertrand Agunmaro Adandé is an archaeologist from the Republic of Benin, born April 7, 1949 in Dakar, Senegal. He completed his primary and secondary studies in Dakar (Senegal), and Porto-Novo (Republic of Benin), between 1954 and 1968. After obtaining his Baccalaureat in 1968, he entered the Institute of Higher Education of Benin in Lomé, Togo; in 1970, he left to continue his studies at the University of PARIS I – Panthéon – Sorbonne in France. There, he obtained a license of history in 1971 and a Master of Arts in 1972. He returned to Benin, where he taught history and geography in secondary schools (1972–1979), before returning to France in 1979 for his doctoral studies. At the University of PARIS I – Panthéon – Sorbonne, he successfully defended a Diploma of Advanced Studies in Archaeology in 1980, and a Ph.D. in 1984. Upon his return, he was sent to the National University of Benin, where he was already a lecturer in archaeology at the Department of History and Archaeology (1978–1986). He taught archaeology as Assistant Professor of Archaeology from 1986 to 1993. Since 1993, he has been a senior lecturer in archaeology. He was Deputy Head of the Department of History and Archaeology of the University of Benin from 1989 to 1995, and Head

Adandé, Alexis B. A., Fig. 1 During fieldwork

of the Archaeological Research Team of Benin (ERAB) from 2003 to 2007 (Fig. 1).

During his career, Dr. Adandé participated in several training courses at archaeological sites in Tunisia and France; in particular at the Pincevent school site, under the direction of Professor André Leroi-Gourhan, College of France (16 June–6 July, 1980) and the training school site of Ras ed. Drak-Kerkouane (Tunisia) under the auspices of the Institute of Art and Archaeology and under the joint direction of Professors A. Fantar and J. Leglay (September 1983).

He has directed several archaeological excavations in Benin. He was, among other things:

- responsible for research and excavations in the region of Allada (1981–1982);
- Co-leader of the Mixed team for the Benin–Togo Archaeological Rescue Project of Mono Valley (1990–1993);
- Co-director of the Archaeological Project in Ouidah (July–August 1991);
- Project Manager of Ouessè Archaeological Research (1992);
- Co-leader of Project Beninese—Danish archaeology (BDArch, 2002–2004).

Dr. Adandé is also interested in museums, where he led several exhibitions within the framework of the development of the archaeological results. This includes the first archaeological exhibition in the Republic of Benin during the commemoration of "Ten years of archaeological research in Benin" (campus of Abomey – Calavi and Honmè Museum – Royal Palace Porto Novo, 1988); and the installation of the exhibition "The Earth is also Our History Book," Alexandre Sènou Adande ethnographic museum, Porto-Novo (1994–1995). He was Executive Director of West African Museums Program (WAMP) from 1995 to 2001. Dr. Adandé has also participated in several seminars and scientific conferences and educational workshops on the national and international level (Fig. 2).

Major Accomplishments

Dr. Alexis Bertrand Agumaro Adandé was the first to have defended a doctoral thesis in archaeology in the Republic of Benin. He was the first archaeologist who conducted well-documented

Adandé, Alexis B. A., Fig. 2 Dr. Alexis Adandé during an exhibition

archaeological excavations at the site of Togoudo Awutè Allada, southern Republic of Benin (Adandé 1984). His work has contributed to the knowledge of the rich archaeological heritage of Benin and its protection. He has contributed to the creation of the Archaeological Research Team of Benin in 1978 under Father François de Medeiros, then Head of Department. This team developed the first national program of archaeological research, covering the territory of Benin and has enabled a precise inventory of archaeological sites in Benin.

Dr. Adandé has contributed to the opening of a regional perspective in archaeological research through the West African Archaeological Association. For him, the archaeological approach, to be meaningful, has to be global; that is to say, the work cannot be achieved without taking into account research sites located in neighboring countries (Adandé 1993). This methodological perspective of integrating the historiography of various countries within the sub-regional West Africa is fruitful, because it helps build hypotheses that are better reasoned and less narrow.

Dr. Adandé also contributed to the training of several generations of archaeologists in Benin and in the sub-region of West Africa. He has significantly contributed to the development of archaeology in Benin and West Africa.

Adaptation in Archaeology

Luis Alberto Borrero
CONICET-IMHICIHU, Buenos Aires, Argentina

Introduction

The theory of evolution is inherently attractive for archaeologists, who are concerned with the long-term history of humankind (Dunnell 1980). Changes through time during the long process of hominization are, by definition, adaptive. Adaptation is clearly one basic constituent of evolution. For that reason, the concept of adaptation – including the capacity for a cultural system to adjust to changes – is important in many approaches, particularly in ecologically oriented archaeology and, more recently, in evolutionary archaeology.

Definition

This variety of approaches using the concept of adaptation naturally leads to the existence of slightly different definitions (O'Brien and Holland 1992; Van Pool 2002).

Basically, adaptation refers to "the idea that organisms are fitted for the particular environments in which they live" (Alexander 1962: 826) or more directly to the "conformity between the organism and its environment" (Pianka 1983: 85).

It is accepted that an adaptation refers to both the state of being adapted and the process that produces the adaptation. However, even biologists have found it difficult to recognize adaptations, and the acceptance that natural selection is not the only mechanism behind evolutionary processes was one result of this difficulty (Vrba and Eldredge 1984).

Historical Background

The concept of adaptation used by many archaeologists was based on the work of classic evolutionary anthropologists like Leslie White (1949) and Julian Steward (1955). In these approaches, tools are seen basically as extrasomatic means of adaptation. The assignation of functions to archaeological tools and features is the key concept to understand and discuss adaptations, an activity that falls within the approach known as cultural evolution, which is extremely popular. Circularity is the main interpretative problem of this approach. Effectively, the role of adaptation as an ex post facto argument invoked as the cause of both the appearance and the persistence of archaeological traits was and is an impediment in most applications (O'Brien and Holland 1992).

On a slightly different vein, Patrick Kirch wrote about "the continuous modification of . . . behavioral patterns in response to changing environments, by means of selective retention of behavior" (Kirch 1980: 110). He explained that it is this selective retention which serves the adaptation of individuals. In a sense, in this approach, artifacts are the result of adaptations. One famous example provided by Kirch refers to the different types of fishhooks recovered at the different Pacific Islands (Kirch 1980). Using this approach to define tactics and strategies which involve tools and features, it is possible to discuss how large parts of past societies functioned in the past, and Kirch used it – in conjunction with historical linguistics – to explain the process of human colonization of the Pacific Islands (Kirch 2010).

One observation is that many times these approaches assumed that cultural systems were in equilibrium and adaptations were simply seen as including those behaviors "that seemed a reasonable way to maintain the status quo" (Kelly

1995: 47). In the end, it is true that the concept of adaptation is trapped in circular thinking.

Since the 1980s, adaptation is also a core concept of Darwinian or selectionist archaeology. In this approach, tools are seen as the hard parts of the human phenotype, and they are treated as adaptations resulting from the action of natural selection (O'Brien and Holland 1992). The problem is that showing that any given trait was under natural selection is a difficult task at best. Most published applications are restricted to highly specific aspects of past societies, like changes in the shape of projectile points or in the wall thickness of pottery (Neff 1992; O'Brien and Holland 1992). These are attractive and useful examples, but wider applications are still difficult to achieve.

Key Issues/Current Debates

In the twenty-first century, different approaches with a focus on the concept of adaptation are disputing their capacity to deal with the archaeological record. Among these approaches, human behavioral ecology (Bird and O'Connell 2006), selectionism (Dunnell 1980), and cultural macroevolution (Prentiss et al. 2009) are among the best known. Behavioral ecology is "the subset of evolutionary ecology that studies the fitness-related behavioral trade-offs that organisms face in particular environments" (Bird and O'Connell 2006: 144) and includes widely used subfields like costly signaling theory. Basic to these approaches is that natural selection provides the flexibility to adapt to a variety of situations. Extensive ethnoarchaeological and experimental research was done in order to understand the costs and benefits of different tools and strategies. These results are in turn used to discuss diverse aspects of the archaeological record that are not focused in adaptations but result from the process of decision-making allowed by natural selection. Ethnographic data is used not only to develop methodological tools but also to test some of the basic assumptions of behavioral ecology.

Selectionism, on the other hand, tries to explain the archaeological record in terms of the direct action of natural selection (Dunnell 1980; Neff 1992). Adherents to this approach believe that ethnoarchaeology is not useful, since recent societies should be the result of evolutionary forces. For that reason, they should not be adequate to provide good analogs for the past. However, there is a role for experiments, especially those designed to develop engineering principles that can be used to understand the performance of archaeological tools. Many of the most attractive discussions about adaptation produced by selectionists derive from this kind of studies.

Researchers working under the cultural macroevolution brand are concentrating in the study of higher-level cultural entities. This is their basis for the construction of an inclusive macroevolutionary approach to archaeology, which is used to study the evolution of whole cultural systems (Prentiss et al. 2009).

Examples of the identification of archaeological and ethnographic adaptations exist, but there are critiques, importantly that most of the so-called adaptations recorded by ethnographic research cannot be the result of natural selection, because they occurred within one human generation. The main example is the use of snowcats by the Cree that replaced snowshoes in a few years (Boone and Smith 1998). It is indeed difficult to implicate natural selection – a benefit in differential survival – to explain a process that occurred in less than one generation. As a result of all these disagreements, nothing close to an operative application of the concept of adaptation for archaeology emerged. Scheinsohn (2011) maintains that the published examples presented as adaptations are many times in fact either aptations or exaptations, that is, "features coopted for a current utility following an origin for a different function (or for no function at all)" (Gould 2002: 1246). In the end, it appears that it is not reproductive but replicative success that is useful in archaeological studies (Leonard and Jones 1987). Tools can be counted through space and time, and the results can be compared. The assumption is that replicative success derives from the better performance properties of tools, and this is something that we can study in a

number of ways. Studies of the resistance of materials, that is, the resistance of ceramics to thermal shock, or the shape of tools, that is, the distribution of cutting edges in lithic tools, can be used to understand the performance potential of different materials. Given the fact that the selective environment is constantly changing, when replication is successful, a number of exaptations are to be expected (Van Pool 2002). For example, most of the morphological transformations of lithic tools are expected to be exaptive. For that reason, it can be suggested that many lithic tools follow an inexorable trend of exaptive transformation. Functional studies, or residue analysis, are adequate ways to study and understand the scope of these variations.

Also, in order to study replicative success per se, engineering studies are useful. These studies are basic components within both the Darwinian or selectionist and behavioral approaches to archaeology. Behavioral archaeology is an approach based on human-artifact interactions that seek to understand cultural change in the long term. In part, this similarity and the idea that "nothing in Darwinian theory per se nor in modern evolutionary biology precludes framing theory and models in behavioral terms" (Schiffer 1996: 96) led Michael Schiffer to propose the existence of important overlaps between both research programs. The answer from the selectionist camp was that differences were still important, including the nomothetic interest which is manifested in the behavioral approach and the corresponding place for historical contingency in the selectionist approach (O'Brien et al. 1998). Beyond these discrepancies, it can be sustained that an understanding of the forces and tensions to which pottery, lithics, or bones are subjected surely helps in the construction of credible adaptive scenarios. These scenarios, in turn, should be able to capture the whole complexity of the cultural systems that produced them.

The study of human bones should be a basic component of any approach that is trying to tackle adaptations in the archaeological record. However, bioanthropology usually appears only through applications of the results of population genetics and molecular biology. This is particularly true in highly speculative scenarios of human colonization of the different regions of the planet. But human bones rarely appear in archaeological discussions of adaptation (but see O'Brien 1987). This is odd, since humans are the carriers of the supposedly adaptive tools and behaviors that we are studying.

Future Directions

One important conclusion is that tools are just means purposefully designed to perform functions. However, intentions can be considered proximate causes at best, and their main role is to generate variation (O'Brien and Holland 1992). Some of the tools recovered in the archaeological record can be seen as exaptations, cases in which the design is not necessarily related with the function but, instead, in the nomenclature of Gould (2002), with its effects. In other words, tools can be used in many unplanned contexts. In one way or the other, it may be true that exaptations can be seen as basic to the understanding of long-term human processes. More specifically, the explicit search for exaptive examples appears today as an archaeologically relevant task, since functions and effects can be understood and temporal changes can be evaluated (Scheinsohn 2011). In a more sophisticated level, exaptations can be invoked even to explain issues like the origins of social inequality or socioeconomic change (Prentiss et al. 2009).

Finally, it is only with the intensive use of bioanthropological information that archaeological discussions of adaptation will find the much desired depth. There is promise in a study that starts with the study of adaptations of the human individual – functional pathologies, stress indicators, stable isotope information, etc. – and then searches for related changes in the frequency of tools or designs. In doing this, we are dealing with conscious or unconscious modifications of behavior (Van Pool 2002: 16) that respond to changes in the social and natural environment. In other words, behaviors, technologies, and phenotypes can be related in complex and difficult to understand loops. Then, an exploration of

exaptations, which may be related or not with previous adaptations, appears to be an attractive and promising way to understand the dynamics of past societies.

Adult Education in Archaeology

Anna Simandiraki-Grimshaw
Department of Classics and Ancient History, University of Exeter, Exeter, UK
Bath Spa University, Bath, UK

Introduction

Archaeology as a discipline has had diverse beginnings and traditions, depending on where it developed and where it is currently practiced on the planet. For example, European archaeology is often (inextricably) entangled with History, Art History, or Classics, while what is called New World archaeology has traditionally been more affiliated with (social, biological, or other types of) anthropology. The demographics and motives of adults involved in archaeology, either professionally or not, are also different, depending on the era and area. As a consequence, the relationship between adult education and archaeology is varied in different parts of the world, but, I would

argue, is seemingly consistent with local preoccupations about heritage and the pasts that archaeology can help illuminate and reconstruct. It is therefore important to look into the relationship between adult education and archaeology, in order not only to understand more broadly the different motivations and pathways of people into archaeological practices and matters but also to consider how the relationship of such people with the past is shaped.

Definition

What is adult education, what is archaeology, and what is adult education in archaeology? For the purposes of this chapter, I take adult education (often interchangeably called Continuing Education or Lifelong Learning, even though they are not the same) to mean training and participation to educational activities by adults who are not (initially or even ultimately) pursuing a professional career in preestablished ways, such as doing a full-time BA. In other words, I take adult education to mean a part-time, ad hoc, non-conventional educational way in which an adult might pursue further knowledge on a specific subject. Such educational provision might be provided by a university, a local authority (e.g., a city council, a museum), a local society, a project, or an interest group. It may range from formalized lessons and assessment, which award certification points or paperwork of some sort, to regular public talks, project outreach (e.g., excavation tours), museum volunteering, etc. Adult education usually covers subjects not taught in school education or school subjects which adult education students did not have the opportunity to study at school initially (due to, e.g., age, academic or vocational orientation, family history, etc.).

I take archaeology to mean both the practice and the subject matter of investigating a past milieu through its material remains, whether this is recent (e.g., World War II archaeology) or chronologically remote (e.g., the Paleolithic). Official practitioners of archaeology are certified as professionals by authoritative bodies, such as university departments or local archaeological services. It is usually they who need to authorize and regulate volunteering in archaeological activities, such as excavations or museum studies, as well as teach archaeological topics in adult education.

Adult education in archaeology, therefore, can be taken to mean here the relationship between usually non-professional education on the one hand and archaeological topics and practice on the other. Consequently, this paper will look at what forms this relationship might take, whether it is reciprocal, what issues it raises, as well as what directions it may assume in the future.

Historical Background

Archaeology as a pursuit, first amateur, then progressively professional, began as the preserve of affluent social classes, especially men. Figures such as Heinrich Schliemann (1822–1890), for instance, exemplify the white affluent male, who, either through inherited or (in his case) acquired wealth, could afford not only the time but also the expense to travel, explore, excavate, and pay for wages and supplies, in order to produce a result with dubious financial but phenomenal publicity returns. This pursuit contributed instead more broadly to the humanistic backlash against the industrial dehumanization of the nineteenth and twentieth centuries CE. Archaeology, like art history, classics, anthropology and other humanities, sought to understand the past through a raft of techniques beyond and in addition to literary analysis, with the ultimate aim of making sense of people in the here and now (in the nineteenth and twentieth centuries) and of imbuing public life with ideas and aspirations about the past, its educational qualities, its nationalist, and even escapist and moralistic qualities (cf. Speight 2011).

By the end of the nineteenth and the beginning of the twentieth century, adult education was making its appearance in earnest. There were several drivers behind the development of this alternative to the traditional, and often elitist, types of education, especially for subjects taught after school (and usually confined to university undergraduates). One reason was the concept of adult education as a social service to educationally

disenfranchised people, e.g., workers, who were seen as both audiences willing to advance their educational background but also as a workforce to be invested in through non-conventional training (whether vocational or not; see, for example, the Workers' Educational Association in the UK, founded in 1903). Another social reason was the wider role that e.g. universities saw themselves as playing in the local communities: Adult education may have represented additional revenue for such institutions, but it also enhanced their reputation as social actors in a world where class boundaries were not as rigid as they had been in previous eras, especially when one takes into consideration the social upheavals afforded by the two World Wars (to variable effect, depending on the country).

The fusion of adult education and archaeology occurred for a number of reasons at the end of the nineteenth and especially the beginning of the twentieth century (see, e.g., Speight 2003). This also goes some way towards explaining the choices of today's students in pursuing adult education archaeology. Some reasons for adult education in archaeology were, from a European perspective, the Enlightenment, the Romanticist and Classicist movements of the eighteenth and nineteenth centuries (cf. Speight 2011), as well as the growing varieties of nationalism, leading up to the early twentieth-century conflicts and beyond. Elite understandings of the past, partly due to antiquarianism but also due to the emerging discipline of archaeology, had seeped into the public domain. This contributed to a climate of public curiosity and excitement about the past which, through "the Grand Tour," museum exhibitions, public lectures, the cinema, excavations, etc., could be more widely and readily accessed. It was therefore an almost natural leap for interested people to want to educate themselves, not just by visiting a museum but by also taking a course, studying how archaeology worked as a discipline, and assessing what it could reveal about past societies, and about students' own ancestors in particular. Another, "New World," reason for the uptake of such education was the sociopolitical circumstances of state formation in countries such as the USA and Australia. This created a wider public interest in anthropological and cultural evolution, often intertwined with claims of land or populace legitimization; but it also helped migrant (and eventually local) communities "connect" to what they perceived as their ancestors.

After the two World Wars, education for archaeology as a discipline, although still the preserve of certifying institutions, became progressively more "democratized" (but less so than other nonhumanities disciplines, such as engineering). So, this incentive, to attend adult education archaeology due to the frequent inaccessibility of university education, was no longer the case. Other reasons persisted or even emerged, such as the movement of feminism and the "need" to find its historical/archaeological antecedents. Recent developments in museological and excavational outreach have also blurred the boundaries between adult education in archaeology and (since at least the 1970s) public archaeology, boundaries once better defined.

Key Issues/Current Debates

So why have students continued to enroll to adult education archaeology courses, instead of, say, taking undergraduate university archaeology courses leading to professional certification? Time and expense are easy (and of course valid) answers. Instead, one way in which to answer this more fully is to look at the makeup of student cohorts and the reasons they give today (author's personal experience). Most adult education archaeology students, whether of a working (evening courses) or retired (day-time courses) background, are of mature age, either living on independent means or day-time jobs or having retired from a profession which was not related to archaeology. Although they can vary widely, most engage in assessment because of a personal passion (which is also why they enroll) rather than an interest in accreditation leading to a professional qualification, which is often an option offered by the providing institution. For many people, enrollment on and study for a course in archaeology are a lifelong aspiration and the

fulfillment of an unrequited parallel occupation with archaeology (i.e., as a recreational rather than a professional activity). Nevertheless, younger students and students systematically working towards accreditation do occur, although they are still the minority. For the non-accreditation students, the outcomes hoped for are varied. Some want to cultivate in themselves a better understanding of certain past societies/civilizations/circumstances (cf. Tennant 1998; Speight 2011: 154 calls it "enrichment learning"). Others want to (and do) volunteer in local communities and heritage activities (cf. discussion in Jack 1980), travel widely, and inform their own practice, if related (e.g., librarianism, museology, school teaching, etc.).

A number of issues can be (and have been, to a certain extent) raised regarding adult education in archaeology. Firstly, because of the complex history of each of the constituent parts, as well as the nature of the fusion between adult education and archaeology, this type of archaeological education might suffer in terms of authority and legitimacy. If this is education which does not produce professionals and which is taught by staff who may or may not have (full or part time) academic positions, it is often the case that courses are considered more simplistic, easier, or inferior to their "certified" equivalents, officially or unofficially (cf. discussion in cf. Speight 2003: 162; also author's personal experience); staff may also occasionally be discriminated against by tenured colleagues as a result.

Secondly, the question of cost and investment arises for adult education archaeology, as it does for all archaeology. Many academic quarters consider the humanities in general, and archaeology in particular, a luxury – and certainly not a wise financial investment. For example, the fees alone for a full time three-year undergraduate degree in archaeology in the UK currently are in the region of £27,000, while a starting salary for a new archaeology graduate is in the region of £17,000–19,000 p.a. (National Careers Service, UK Government 2018), if s/he is lucky enough to be employed. This long-term issue has prompted archaeology as a discipline to react in three ways:

(a) To divide between "hard-science" archaeology (incorporating chemistry, geophysics, palaeopathology, and the like) and "soft-science" (such as more theoretical, classicist, epigraphic, and art historical approaches)
(b) To market itself as providing transferrable job skills if an archaeological career is not pursued (but see discussion in Colley 2005 for the potential non-effectiveness of this)
(c) To use adult education archaeology as a way of sensitizing the public about the usefulness (and financial needs!) of archaeological investigation and as a way to redress the gap of staff unemployment, audience curiosities and aspirations, and outreach quota.

This, in turn, raises the question of who is driving the adult education archaeology agenda. Currently, it is almost always a top-down process, primarily determined by staff and institutions (who offer courses), then by student demand (who take or do not take the courses on offer, and can, on occasion, suggest topics to staff, but normally do not organize their own).

Ultimately, adult education in archaeology currently operates, as does much of the wider adult education sector in this author's opinion, as an add-on to mainstream institutional provision and to students' lives and careers, rather than as an essential type of training or set of skills needed in employment, cognitive development, and health or everyday activities. This is certainly not the design or intent of either the adult educational providers or the students who take the relevant courses. The source is likely to be found on an institutional, governmental, and museological level, as it is these actors who determine the societal and employability role of archaeology (cf. debate on instrumentalism in Hamilakis 2004), and therefore, in effect, regulate how the different pathways to archaeological knowledge are perceived, achieved, and (not) certified.

International Perspectives

The author has extensive knowledge and experience of the Higher Education and Adult

(Continuing) Education sector in the UK, principally through archaeology, Classics and art history. The view from this position is situated within the wider milieu described above. However, it is also complemented by the particularities of the UK educational provision, such as university and local authority Continuing Education Departments, UK organizations creating or promoting accessible archaeological knowledge, as well as the UK governments' changing attitude to archaeology specifically and to adult education more generally. For example, universities with substantial reputation in (traditional) archaeological training and practice, such as Oxford, Cambridge, and UCL, also, unsurprisingly, offer well-attended adult education archaeology, which recruits well and offers topics of both local and international archaeology. Local authorities and archaeological societies may offer a comparably wide range of topics, but students who attend these are more likely to enroll on courses which investigate their local archaeology (e.g., Roman Britain; cf. discussion on regionalism in Speight 2003: 154) rather than a completely new or geographically remote archaeology (e.g., Minoan Crete), although there are, of course, exceptions.

There is also variation in the organizational and financial aspect of adult education in archaeology. Larger, longer established, and well-funded education providers, such as universities, attract students not only because of the range of archaeological topics they make available but also because of their reputation (both as institutions and as staff), online provision (e.g., distance learning), location, and other attractive additions to their "package" (Fig. 1; e.g., the opportunity to spend time exploring the institution and surroundings during a weekend course or summer school; cf. Speight 2003 for a thorough, contextual overview of the UK residential sector).

Adult Education in Archaeology, Fig. 1 *Learning Environment*: (**a**) exterior of Dillington House, Ilminster, UK, host of one of the author's Continuing Education courses (in this case, Aegean Prehistory and Early Iron Age Greek Archaeology), May-June 2014; (**b**) typical adult learner classroom arrangement for another of the author's residential courses in archaeology (in this case, Aegean Prehistory), at the Institute of Continuing Education (ICE), Madingley Hall, University of Cambridge, Cambridge, UK, October 2016; (**c**) props (including replicas of vessels, tablets, seals and tools) and other materials towards the provision of a multimodal and tailored learning experience from the same occasion as **b**. Photography for (**a**) by and © of T. Grimshaw, 2014, reproduced here with permission; photography for (**b**) and (**c**) by and © of the author 2016

In addition, they operate on an economies-of-scale model. In other words, the overall revenue of a university Continuing Education department makes it possible to be flexible regarding recruitment numbers, which can vary substantially between courses. So, for example, the lowest viable number of students for an adult education course in archaeology to run at a university setting is 6, bearing in mind that there may be several other courses which recruit in the region of 20–25 students, and therefore even out the projected earnings of the department, the latter managed by professional academic staff. In addition, in these cases the premises need to be booked but not hired (i.e. paid for separately) and there is administrative and library support. The same is not the case for a course organized by proactive volunteers on the level of a local archaeological society, museum, or interest group. They have to manage all the administrative, financial, booking, and other practicalities on an ad hoc basis, hire venues at additional cost and effort, liaise with the teaching staff, sort out taxes etc. So, for these courses, which do not come under a larger university or departmental umbrella, a viable minimum number of students is about three times more, in the region of 18–20 at least, which, in turn, limits the range of courses on offer, and therefore, eliminates "tasters" of initially less popular but probably just as interesting and inspiring archaeological subjects.

One additional point should be made here regarding the financing of adult education in archaeology. Up until 2006, the UK government offered part-sponsorship of adult education / lifelong learning courses in general. This was done for various reasons. One of these was to help more people access educational provision and gain a variety of skills (academic, vocational, personal, social, etc.). Another reason, bearing in mind that many, if not the majority, of adult education students were and are pensioners, was to help elderly people keep an active mind as a strategy towards social interaction and as a prevention of conditions such as dementia (cf. Kingston 2006). In 2006, the UK found it appropriate to radically restructure such funding. This had a profound and immediate effect. Firstly, it led to a sharp drop in the number of students who could afford to pay for courses and to the axing of many courses which either the providing organizations or the enrolling students did not feel were a priority, now that there was more competition for money. Secondly, the change directly affected archaeological provision, such as in the case of the University of Bristol, which had to close down its archaeological programs for the wider public (these, up until then, were prominent in the local community). Thirdly, as a knock-on effect, departments as a whole found it difficult to continue not only with the breadth of courses that they once offered, but to continue at all. The Continuing Education Department of the University of Reading was one such fatality, and so the local adult education provision was eventually taken over by the Department for Continuing Education of Oxford University, which hired the spaces on Reading University's campus in order to run its courses. Archaeology, as part of this sector, felt these repercussions more acutely, as students now had to prioritize their sponsorship in a way that had more to do with instrumental gains (e.g., learning mainstream foreign languages) rather than non-practiced personal fulfillment (e.g., broadening their historical-archaeological knowledge). In effect, archaeology and its adult education provision almost reverted to the nineteenth century paradigm of an affluent, elitist pursuit.

Future Directions

The future of adult education in archaeology may be bright or bleak based on a number of factors. It could be bleak if funding for it and archaeology as a discipline continues to shrink. There is only so much effort and cost that educational organizations, societies, and individuals can invest in something which is considered as a luxury or add-on by some of the same organizations and the governments they operate under and are (not) sponsored by. It can also be bleak if the rift in archaeology itself widens further, with the "hard-science" branch, already largely inaccessible by

nonprofessionals, providing exclusive training to practitioners, and the "soft-science" part catering for more philosophical (and increasingly more detached from fieldwork) aspects of archaeology. Thirdly, it can be bleak depending on the demographics of the adult education archaeology students of the future. If in 20–30 years' time the cohorts continue to be made up of mature students, it is doubtful to what extent the social, professional, and personal interests of today's youth would be translated into fees paid, in their maturity, into archaeological knowledge for the wider public; or even if the nature of education sought would be the same. Conversely, if the demographic age of such students decreases, i.e., is brought down to working ages for a larger proportion of the students, it is likely that these people would be more interested in being instrumental by acquiring transferrable, practical, archaeological skills, rather than pursuing a more rounded, less quantifiable education. This, in turn, would kill off part of the discipline and theory of archaeology.

Conversely, the future of adult education in archaeology may be bright. At a time of great turmoil, migration, culture clashes, conflicting accounts of the present and the past, as well as a number of crises, students, and indeed adult educators, (should) seek to educate themselves regarding how past populations dealt with some challenges, in the hope of understanding their own positions and options in the here and now (cf. discussion in Guy 1999 about the cultural relevance of adult education; and in Colley 2005, esp. 62, and Simandiraki-Grimshaw 2017 about the current public relevance of archaeological education in the USA, Australia and Greece respectively). Another reason why organizations, associations, local authorities, and interest groups persist in pursuing archaeological knowledge, despite the effort and cost (and often travel) involved, is cultural capital. Understanding past civilizations, learning to be analytical and critical of sources, relics, and situations, and synthesizing narratives based on a variety of data (excavational, epigraphic, osteological, art historical, chemical, etc.), as well as understanding how local and global identities were and are constructed, should be seen as skills that current societies need (e.g., Tennant 1998). They should not be seen as luxuries or optional add-ons left to the discretion of organizations, adult education staff, or interested individuals. They ought to be funded, promoted, and supported through infrastructure, public debates and legislation. It is this author's wish and hope, therefore, that this will have been achieved by the next generation of adult education staff and students of archaeology.

Acknowledgments The author would like to thank Prof. C. Smith, as well as the anonymous peer reviewer(s) for their valuable help. She would also like to thank all students and educational colleagues who provided the experience and inspiration for the contents of this paper.

Advertising and the Appropriation of Culture

Traci Ardren
Department of Anthropology, University of Miami, Coral Gables, FL, USA

Introduction

The growth of cultural tourism and the spread of global information have both contributed to an increase in the commercialization of the past. Ancient cultures are used for marketing everything from vacation destinations to a wide range of products that draw upon stereotypes of the past as mysterious or idyllic. The pervasive use of ancient sites and artifacts by advertisers may simultaneously increase awareness of the past as well as put sites in danger as a result of overvisitation or mismanagement.

Definition

Certain sites such as Stonehenge and Chichen Itza have both iconic status within modern Western marketing and clear brand name recognition. Unfortunately, the field of advertising is largely unaware of the impact upon archaeological sites and descendant communities of a campaign designed around stereotypes of the past.

Key Issues/Current Debates/Future Directions/Examples

Advertising is ubiquitous in our world today. Given the seemingly endless opportunities to purchase goods and services in modern Western society, it is no wonder that archaeological cultures and sites are frequently used to attract consumer attention. Well-known archaeological sites achieve an iconic status within many cultures and become easy shorthand for specific values advertisers wish to associate with their products. The advertising industry is voracious and constantly on the lookout for new ideas and ways to market products. Archaeologists must be aware of the impact such media campaigns have on popular conceptualizations of cultural heritage and guard against a trivialization of archaeological resources due to overexposure or distortion in the media.

One of the risks of archaeological resources being utilized in advertising campaigns derives from the nature of this particular enterprise. "Advertizing is a rhetoric of persuasion, not a narrative of instruction," and while it is obvious that we do not turn to advertisements for educational purposes, nonetheless the messages conveyed about ancient cultures and archaeological sites via the medium of advertising influence our shared understanding of the past (Talalay 2004: 208). In many cases, an entire civilization is reduced to a single image and concept – when Stonehenge is used to convey a sense of a premodern, nonindustrial, and tribal identity missing from today's hectic world or when a jungle-covered Maya pyramid is used to convey an exotic and dangerous escape from modern routines, advertisers have selectively imagined the past in a way that essentializes the diversity and complexity of ancient cultures in order to connect quickly and easily with the consumer (McCarthy 2002). This reductive process in turn fosters the stereotypes that most Westerners have about the ancient past – that it was a simpler, easier time – and may even constrain how heritage resources are managed. The use of a single icon from ancient Egypt, such as the Sphinx, reinforces the stereotype that ancient Egypt was dominated by isolated monumental constructions that exist in a peopleless and pristine setting (Macdonald and Rice 2003). When such extraordinary and unusual artifacts come to define an ancient culture, we lose the richness of a landscape filled with ancient people performing an enormous range of activities in order to keep desert settlements functioning, and in turn we hamper our ability to preserve the less visible sites where the vast majority of the population lived, worked, and conducted the business of social reproduction.

Popular advertising that utilizes archaeological themes often overemphasizes the artificial

boundary erected today between past and present (Talalay 2004). The idea of a "past" that is not in some way tied to our modern lives is a falsehood encouraged by depictions of archaeological cultures as exotic, unchanging, or bizarre. Advertisements for adventure tourism or all-terrain vehicles often utilize this trope by situating the modern consumer within an alien landscape of ruined structures in a harsh environment. The message conveyed is that the past is stuck in the past and we may enter it for entertainment or diversion if we are brave enough. Advertisements for cosmetics and jewelry that draw selectively upon artifacts and iconography of the ancient Mediterranean, for example, are based in a different trope that argues the boundary between past and present is permeable – certain goods have always been valued by elites, and the purchase of a pearl necklace or timepiece will connect the consumer to a privileged set who unabashedly displayed their elite status when such behaviors were better tolerated (Duke 2007). The consumer is invited to share an essential understanding of the unchanging and timeless value of certain important luxuries. In both cases, whether the past is depicted as alien and threatening or as a source of legitimization, the past has an uncontested authority that advertisers use to promote their product. This inherent authority is set in opposition to our ever-changing present, full of diverse choices and ambiguity.

Archaeological tourism is one venue in which advertisers take full advantage of ancient cultures to sell a product. As cultural and heritage tourism have grown over the last 20 years, national tourism agencies have created marketing campaigns centered on the iconic image of archaeology as healthy escapism. Many of the most important archaeological sites around the world are state owned and state managed, with governmental control over how they are marketed. This arrangement has serious implications for the interpretation of archaeological cultures, as governmental control has often meant a small minority of power holders construct a past that is acceptable, marketable, and profitable. Descendant communities, especially indigenous populations, are very often excluded from this interpretive process and from decisions about how their heritage will be marketed or appropriated for national tourism campaigns (Ardren 2004). This is despite overwhelming evidence of the strong ties many modern indigenous people have to ancient sites or to an identity that rests in part within a historically charged landscape of places and events. In January 2006, indigenous people from all over the world met at the ancient center of Tiwanaku, Bolivia, to witness purification and blessing ceremonies of incoming President Evo Morales. President Morales is the first Bolivian president of indigenous heritage, and he chose Tiwanaku as his inauguration setting deliberately. His comments on that occasion referenced the archaeological site as evidence for the survival of indigenous culture and its successful resistance to colonial empires. Morales reclaimed the site as a reservoir of native art and culture as well as a source of tourism revenue. The distinctive art and architecture of Tiwanaku are frequently used in advertisements, and President Morales argued that the indigenous people of Ecuador should have a role in deciding how such images are commercialized and manipulated. Tiwanaku is by no means a unique example: the three most heavily visited UNESCO World Heritage sites in the New World – Chaco Canyon in New Mexico, Chichen Itza in Mexico, and Machu Picchu in Peru – have no formalized mechanisms for the involvement of the large descendant communities that surround them in decisions about how images from the sites will be commercialized and popularized.

The way archaeological resources are portrayed in the media also affects the public understanding of archaeology as a natural and cultural resource and, thus, site management strategies. If archaeological sites are trivialized, through their depiction as either the settings for escapism or entertainment activities only, the argument for sufficient resources for protection and maintenance becomes much harder for archaeologists and others committed to heritage preservation to make. Likewise, when archaeological sites are depicted as exotic locations full of unusual or mysterious objects, a message is conveyed that archaeological resources are only located in distant places and we are unlikely to

encounter them at home. When archaeological cultures are used as a passive backdrop for commercialized advertising, a dangerous impression is given that archaeological resources are unlimited and eternal and that they exist without the need for careful preservation and management (McCarthy 2002).

In sum, the archaeological past is generally appropriated by advertising in a way that furthers common stereotypes and does not encourage responsible use. Improvements are simple and would involve avoidance of these stereotypes, efforts to "people" the past, and consultation with descendent communities when images are being used. The common use of ancient cultures in modern advertising can have a very positive effect upon the public awareness of archaeology and archaeological resources. But there is tremendous room for improvement in how such images are utilized and in trying to understand the effect they have on all of us who consume them.

Aerial and Satellite Remote Sensing in Archaeology

Douglas C. Comer
ICOMOS International Scientific Committee on Archaeological Heritage Management (ICAHM), Cultural Site Research and Management, Inc. (CSRM), Baltimore, MD, USA

Introduction

Aerial and satellite remote sensing technologies offer a noninvasive and nondestructive tool that can be used in many ways for the preservation and conservation of archaeological sites and landscapes. A synoptic, landscape perspective is inherent in the use of these technologies, which enriches the context that is essential to understanding the value of archaeological discoveries. The extent and nature of environmental changes that threaten sites can often be more quickly observed, characterized, and measured by observing the landscape from above, rather than exploring it on the ground. With training, archaeologists can use them to (1) directly detect archaeological sites, (2) model likely site locations, (3) assess the importance of sites based upon spatial relationships among sites themselves as well as relationships among sites and environmental features, (4) detect threats to sites and landscapes arising from natural processes or from development, and

(5) monitor such threats as they emerge, increase, or abate.

Recent years have seen enormous advances in sensor technologies and much greater access to a variety of aerial and satellite platforms that carry these sensors. During the same period, computing power measured in numerous ways has roughly doubled every two years ("Moore's Law"), data storage capacity has grown at the same pace and become much less expensive, and software for enhancement, analysis, and integration of images into geographical information systems has become more user friendly. Some of this software is open source or available at a reasonable price. The cost of using open source software is therefore only in acquiring the training necessary to use it. The result of these technological improvements means that little stands in the way of their use by archaeologists and conservationists.

Definition

Remote sensing includes a wide array of technologies that have in common the acquisition of data from platforms that are at a distance from objects, materials, and other phenomena of interest. These technologies use and analyze electromagnetic radiation or, in a few cases, sound waves or gravitational fields. Types of radiation frequently used include many bands of the electromagnetic spectrum, from ultraviolet through visible light to longer electromagnetic waves, such as near infrared, infrared, and radar. Sensors that collect data generated by the use of visible through infrared bands are termed *multispectral* if they utilize only a few, narrow, discreet bands or *hyperspectral* if they sense bands over a continuous range. Some electromagnetic bands can be transmitted and received in ways that greatly enhance the ability to collect data of particular interest. Light waves, for example, can be made highly coherent and focused. Transmitting and receiving a pinpoint of light created in this way can be used to precisely locate what reflected the light. Using many points of light, a surface can be extrapolated from multiple locations. Radar transmitted from a rapidly moving platform (aircraft or satellite) creates a synthetically large antenna; since resolution of images sensed by radar depends upon the size of the antenna, the faster the platform carrying radar moves, the greater the resolution of resulting images.

Synthetic aperture radar (SAR) waves can also be polarized vertically or horizontally at transmission and reception, providing data that can be used to discern shape and orientation and can be analyzed interferometrically to develop a surface model. Analysis of remotely sensed data is done with use of many different types of software that create and enhance images, and provide built-in algorithms for the analysis of images and a degree of capacity to develop custom algorithms. Images, which are enhanced, analyzed, or otherwise modified, are often further interpreted as a layer in a geographical information system project. Data obtained from sensors and images can also be analyzed with mathematical, statistical, and engineering software.

Key Issues/Current Debates/Future Directions/Examples

An important application of this technology is the detection of archaeological sites. Archaeologists have used aerial photos obtained from aircrafts and before that balloons and kites for more than 100 years (see, for example, Poidebard 1934). Photos obtained from small, private aircrafts are still being used in this way, especially in Europe and the Middle East. From 1960 to 1972, the United States operated the Cold War-era CORONA intelligence satellite program. In 1972, Corona images were declassified and now can be easily obtained by the public (http://earthexplorer.usgs.gov), as can those acquired by a companion satellite, GAMBIT. These black and white photos are of relatively high resolution, but were not georeferenced and contained the normal distortion associated with perspective. They require georeferencing or preferably orthorectification to be transformed into an image with a scale that is constant throughout. They have been of especially great utility in planning archaeological surveys in remote areas and in

determining the locations of sites that have been obscured or obliterated by development. Min (2013) has used CORONA photographs in this way to map features on the ancient landscape that have been removed by the recent rapid development in China.

New analytical techniques can render the analysis of images produced with older, strictly optical, technologies more useful. Jesse Casana and Jackson Cothren (2013) of CAST at the University of Arkansas have developed a means to streamline orthorectification of CORONA imagery. They have made more than 1000 CORONA tiles of the Middle East available for download (http://corona.cast.uark.edu/index) and have described their technique for replication by others. Ur (2012) provides an overview of how CORONA and GAMBIT have been used in the Middle East, describing how tells, roads and tracks, irrigation canals, and fields have been discerned with the eye by attention to shadow, lightness, and darkness. Ur and Menze have refined this approach by developing signatures for soils generated by human occupation (anthrosols) using bands from among the 14 collected by ASTER satellites (Menze and Ur 2013).

Newer sensing technologies expand possibilities for site detection. If archaeological remains are above ground, and exhibit a level of structural integrity, LiDAR can generate remarkably clear images of them. If dense clusters of LiDAR beams are used, the full array of archaeological features on a landscape can be imaged even when covered by forests, shrubs, or grassland. SAR can penetrate materials to a depth determined by wavelength and moisture content of materials encountered. Maximum penetration is of sand in hyperarid environments. SAR images are less easy to interpret with the naked eye than are images produced by LiDAR, because data to produce them are obtained from oblique angles, and so distortion can be more difficult to correct. SAR images are therefore generally more informative when data contained in them are analyzed by the use of statistical protocols that have been identified or developed for this purpose (Comer and Blom 2007; Chen et al. 2013). Similar statistical protocols can also detect sites using multispectral and hyperspectral imagery under certain conditions with greater or lesser success given the nature of sites to be detected and the environment in which they are located. Statistically based site detection, by definition, admits some degree of uncertainly until site locations are confirmed on the ground. Nonetheless, an inventory based upon statistically valid measures of productivity and reliability provides a valuable starting point for site protection, one that can also be used to more wisely allocate on-ground survey efforts. An alternate approach is the use of archaeological predictive modeling (APM), which identifies areas more or less likely to contain sites. While direct detection of archaeological sites can therefore be termed probabilistic, APMs are *possibilistic*, as discussed by Van Leusen and Kamermans (2005: 30).

Site evaluation is an essential step in the protection of archaeological heritage. Not all sites and landscapes are of equal importance. Given the dearth of resources available for site preservation, setting priorities is essential. The analysis of multispectral and hyperspectral imagery is particularly useful in characterizing the environments in which sites occur. It can therefore illuminate relationships among sites themselves and the environment in which they are found. These relationships have a tremendous bearing on the importance of each individual site. Environments can often be characterized sufficiently using data contained in inexpensive NASA satellite imagery. Landsat satellite images are now available at no cost, and the cost of ASTER imagery is minimal. Comer (2013), for example, has used Landsat imagery to explore the association between the distribution of sites on arable soils and the emergences of settled way of life among the Nabataeans.

NASA satellites also provide information not available from imagery collected by more recently developed, higher-resolution satellites operated by the private sector: they provide a record of environmental change over the past 30 years, since the first Landsat was launched. This records degradation that affects the value of sites, which can be halted or reversed if detected in time. For example, Barlindhaug et al. (2007) has analyzed Landsat imagery to monitor regrowth at

archaeological sites allocated in abandoned farms in Norway, which damages or destroys them.

Precise surface models (DSMs, DTMs, and DEMs) can be the key to an even deeper understanding of intra-site and environmental relationships. These are developed from dense point clouds, often obtained using LiDAR and SAR data collected from satellites and many common types of aircraft. As noted previously, data collected by LiDAR, if this is done in certain ways, can model the surface of the earth as it would appear if it were devoid of vegetation (usually termed a digital terrain model or DTM). Standard or custom algorithms can generate least-cost paths from DTMs. These provide the basis for developing and testing hypotheses about polity size, procurement zones, and social and political interactions. White and Surface-Evans (2012) offer many examples of how this has been done; surface models can also provide viewshed analyses, which are pertinent to suggesting similar social parameters (Fisher and Farrelly 1997; Bongers et al. 2011). Harrower (2010) and Harrower et al. (2011) has generated hydrological models from digital surface models that clarify the development of agriculture and the role of pastoralism in Yemen.

Surface models can also identify areas that would visually intrude upon ancient landscapes were they developed. They can also be used to model hydrological changes that threaten archaeological sites (Akasheh 2012). Point clouds can be generated by photogrammetric analysis of "stereo pairs" acquired from model airplanes and even kites. This can be done very inexpensively, but will not provide a DTM.

As the cost of such technologies continues to lessen, archaeologists, conservationists, and cultural management officials will increasingly use them to track and maintain cultural heritage throughout the world.

Aerial Archaeology

Włodzimierz Rączkowski
Institute of Archaeology, Adam Mickiewicz University, Poznań, Poland

State of Knowledge and Current Debates

Aerial archaeology (AA) uses photographs, and other kinds of image acquisition, in archaeological field research. It involves taking photographs of the land from above, examining them for pertinent information, interpreting the images seen there and making the resulting data available in a variety of forms to develop archaeological knowledge about past people and the conservation of archaeological sites and landscapes (Bewley and Rączkowski 2002).

Why Can We See Variety Types of Sites?

Since people first learnt to fly, it has been appreciated that traces of early human activity can be observed from the air, recognized from their

Aerial Archaeology, Fig. 1 Bonikowo, Wielkopolska Region, Poland. Early Medieval stronghold clearly visible due to flooded bottom of valley (Photo: W. Rączkowski, March 1999)

curved or linear shapes. Humans have always exploited and adapted the environment to their own needs. The surface of the ground has been disturbed and altered by generations of previous occupants, who have dug into it to create foundations, ditches and pits, and raised structures upon it, in the form of stone buildings or earth ramparts and mounds. All this activity has caused "injury" to the land. Much of it has been subsequently covered over or levelled by later exploitation, particularly agriculture. Today, in the majority of such places, there is little sign of this past human activity on the surface, but the "scars" remain beneath and these may show up from the air (Wilson 1982).

Some ancient earth, stone, and timber structures are still just visible above ground level as *earthworks*. Most frequently encountered are the remains of barrows, ramparts, walls, banks, and ditches. These can be photographed by exploiting the contrast of the shadows by a sun low on the horizon. The way snow settles and melts may also reveal the presence of archaeological features, as can widespread flooding (mainly on low-lying ground) for it exposes all the topographic elements which are above water level (Fig. 1). The new technique of LiDAR (see below) now records low-lying earthworks by measuring their topography directly.

The remains of human activity beneath the topsoil determine growth conditions and cause difference in growth, causing *cropmarks* (Fig. 2). Subsurface hollows, foundation trenches, ditches, and pits retain water and nourishment, prompting the plants that grow immediately above them to be taller or greener for longer than others in the immediate vicinity (*positive cropmarks*). Plants growing over stones, bricks, or roads are deprived of moisture, so may be more stunted in growth and more pallid in color (*negative cropmarks*). Cropmarks can also be photographed thanks to the shadows thrown by taller plants, disclosing the archaeological features beneath. Not all plants are equally "sensitive" to variable soil conditions – some "display" what is beneath the topsoil, while others do not react to local conditions. Wheat and barley best show the presence of archaeological remains well, especially late in the growing

Aerial Archaeology, Fig. 2 Mutowo, Wielkopolska Region, Poland. Cropmarks show up archaeological remains of a medieval town (thirteenth century) of Szamotuły (Photo: W. Rączkowski, July 2006)

season, while potatoes, cabbage, or corn are less demonstrative of what lies beneath.

Plowing may disturb the uppermost layer of an archaeological feature and bring it to the surface as a *soilmark*, recognizable by its different color to the topsoil. Soilmarks can be most readily observed when there is no vegetation growing – from late autumn through to early spring (Fig. 3).

Development of Techniques: History

The first known aerial photographs of archaeological sites were taken between 1899 and 1911 (Forum Romanum, Tiber delta, Pompei, Ostia) and in 1906 (Stonehenge). The hot air balloons were used to take cameras into air. The First World War advanced the development of both aeroplanes and cameras. The number of pioneers using aerial photographs to search, identify, and document archaeological sites increased (T. Wiegand, L. Rey, G. Beazeley, A. Poidebard, C. Schuchhardt). O.G.S. Crawford (1923) made a significant contribution to the methodology and its application in research. In the 1920s and 1930s, photographs were taken of archaeological sites (e.g., hillforts) across Europe, excavation work in progress was documented from balloons and aircrafts (e.g., Biskupin in Poland), and aerial surveys led to the discovery of new sites (e.g., Woodhenge – UK, Ipf near Bopfingen – Germany). Similar surveys were also successful in the USA (C. A. Lindbergh, N. Judd), Mexico (A. V. Kidder, P. C. Madeira Jr.), and Peru (G. Johnson).

Developments in both technology and the interpretation of aerial photographs (e.g., the Allied Central Interpretation Unit) during the Second World War enhanced the technique and established it after the war as a primary research tool in archaeology. Although political regimes in some European countries severely restricted overflying, it developed without major interference in the UK (J.K. St Joseph, A. Baker, J. Pickering, D. Riley, D. Wilson), France (J. Baradez, R. Agache), West Germany (I. Scollar,

Aerial Archaeology, Fig. 3 Rębowo, Wielkopolska Region, Poland. Colour of soil differentiation show up the remains of a plowed rampart of an early medieval stronghold (Photo: W. Rączkowski, March 1999)

R. Christlein, P. Filtzinger, O. Braasch, K. Leidorf), Belgium (C. Leva, J. Semey), and Denmark (H. Stiesdal). The 1994 Klienmachnow conference (in Germany) was a key moment in raising awareness of AA among archaeologists from Central, Eastern, and Southern Europe.

Stereoscopy was a successful technology especially applied during WWII. Nowadays, it is frequently used in AA when working with vertical photographs to give an illusion of depth. A 3D effect can be achieved using two photographs offset by 60%. The stereoscope shows the left eye one photograph and the right eye the second, the brain then creates a 3D image of the area.

Since the late 1960s, AA has seen dramatic technical advances. In addition to the traditional platforms (e.g., kites, model planes, balloons, aircrafts, helicopters), remote sensing now makes use of multispectral imagery captured by *satellites* to explore past landscapes and features at a wide range of scales. Satellites (since 1960s) orbiting at 600–1200 km from the earth's surface have recorded a wealth of information.

The declassification by the USA in 1995 of an archive of images acquired by the first generation of US photo reconnaissance satellites (CORONA – 1960 and 1972) and the KH-7 GAMBIT and KH-9 mapping camera programs in 2002 was a milestone for archaeologists who quickly recognized the potential of these archives for extensive survey coverage of the Earth, including territories currently lying in no-fly zones (e.g., Turkey, Syria, Armenia) (Ur 2003). The ERTS satellite (later renamed LANDSAT) was launched in 1972 to continually photograph the Earth's surface. Many countries and organizations have sent satellites equipped with cameras and sensors into orbit to acquire information on surface events by using electromagnetic radiation across the spectrum (Parcak 2009; Lasaponara and Masini 2012).

Use of the wider spectrum of different bands of wavelengths of electromagnetic radiation (daylight, infrared, ultraviolet, thermal radiation) means that AA can be classed as a method of *remote sensing*. Radiation of different wavelengths detects different physical features. The majority of satellite survey work in archaeology

has focused on the band of *visible light* to detect archaeological features and past landscapes. However, visual data are only a small proportion of what cameras and other sensors can detect. A multispectral scanner registers a small number of bandwidths. By comparison, a hyperspectral scanner registers 100 or more bandwidths – including those which are beyond the visible spectrum, e.g., radar, ultraviolet, thermal radiation.

For assessing what can be detected, two parameters are especially important – spectral resolution and spatial resolution. *Spectral resolution* denotes the detection that is possible owed to the chosen wavelength. The range of visible light is from 0.380 to 0.780 μm (panchromatic image). If a sensor registers visible light, then it covers four channels (spectrum bands) – blue (0.45–0.52 μm), green (0.52–0.60 μm), red (0.63–0.69 μm), and infrared (0.76–0.90 μm). The spectral response pattern of soil is generally governed by the properties of the soils: color, texture, structure, mineralogy, organic matter, free carbonates, salinity, moisture, and the oxides/hydroxides of iron and manganese. Thus, analysis of results from parts of the spectrum provides information about the physical-chemical characteristics of any detected features. For example, analysis of green and red bands may give information on the contents of iron (Fe) in soil. *Normalized Difference Vegetation Index* (red and infrared bands) is a method for measuring vegetation vigor, which may indirectly infer the presence of archaeological features.

Ground (spatial) resolution measures the minimum size of a feature detectable on the ground. A feature larger than the spatial resolution will be visible on the image, while a feature appearing smaller than a pixel on the image will not be seen. High ground resolution therefore is extremely important. Images of 80 m resolution (Landsat series MSS 1, 2, and 3) or 30 m (Landsat TM 4 and 5) are sufficient to determine geological or geographical aspects but not to detect archaeological features. Current resolutions can be achieved down to 1 m, which enables individual features such as storage pits, barrows, or sunken houses to be identified. The IKONOS satellite's panchromatic imaging (the whole visible spectrum, which means more energy reaches the sensor) provides a surface resolution of 1 m, although multispectral imaging resolution falls to 4 m. Satellite images (mostly optical, high resolution) are currently used in prospection of archaeological features, study of their environmental contexts, spatial analysis, past landscape studies, 3D modeling, preservation assessments, protection, and management of archaeological heritage.

Airborne Laser Scanning (ALS) developed in the 1990s uses the LiDAR (**Li**ght **D**etection **a**nd **R**anging) system for rapid, high precision survey of the surface of the ground (including forested areas) (Crutchley and Crow 2009). In this method, laser range-finding beams are fired at the ground from an aircraft with exact position measured by GPS, creating clouds of points (with x, y, z coordinates), which are used to compute a digital terrain model (DTM) and digital elevation model (DEM) (Bewley et al. 2005). Digital graphic processing generates views of the surface in microrelief. The most spectacular discoveries made using this technique include medieval field systems, road courses, barrows, queries, etc., especially those hidden in forests (Devereux et al. 2005, Doneus and Briese 2011) (Fig. 4).

Aerial Archaeology, Fig. 4 Wrześnica, Pomerania Region, Poland. DTM derived from LiDAR of the forested area presenting detailed topography and showing up the presence of geomorphologic structures as well as clusters of early medieval burial mounds (By Ł. Banaszek & MGGP Areo, 2012)

LiDAR data also provide additional information on the intensity of the reflected light, as the emitted signal is usually in the near-infrared (NIR) spectrum. It is therefore possible to use it to analyze moisture, chlorophyll content, and other factors that characterizes cropmarks.

Theoretical Context

AA has been a key branch of *field archaeology* for more than a century. Its initial success was applied to generating *culture history*, featuring interpretations based on *evolution* and *diffusion*. This took the premise that a photograph is neutral and objective in its representation of the world. As image registration is "mechanical" in nature, photographs were seen as recording real anomalies devoid of a subjective human factor. These anomalies added to the world's stock of sites and monuments, from which the narratives of prehistory and history can be written. By the same token, repeat visits to certain landscapes led to the realization that the sites were disappearing. *A Matter of Time* (published in 1960 by the Royal Commission on Historical Monuments of England) established a role for AA in conservation practice in the UK, leading to *The National Mapping Programme* and the development of set standards.

Processual archaeology was a major factor in the technological "revolution" in AA. It emphasized the objectivity of the research process and the consequent importance of the precise measuring of cultural and natural features. This mission was aided by new analytical technologies, particularly computerized *data bases* (including mapping) and *Geographic Information Systems* (GIS). Gaps in the record raised questions about the visibility of sites, and prompted research into *formation processes* as applied to cropmarks and soilmarks. Results obtained from remote sensing influenced the classification and construction of models describing the relation between cultural systems and the natural environment and the application of technological innovation.

Postprocessual archaeology questioned the "realism" of aerial photographs and emphasized the role of perception and interpretation in the creation of the record. Interpretation issues are the subject of intense discussion on the way the cultural context affects aerial survey, the photo-reading process, and their role in forming how we imagine the past (Brophy and Cowley 2005).

Interpretation

Understanding that there is an interpretative process by which the information from aerial photograph becomes an archaeological record is crucial. The interpretation of archaeological features and landscapes is a skill built on experience and knowledge, where intuition and subjective judgment are acknowledged as major factors. The ability of the archaeologist to interpret and depict is as important as the technical processes of rectification and georeferencing.

As archaeological use of digitally recorded data has developed, it has become increasingly clear that it is not an "objective" dataset. Methods of primary data collection and processing parameters have a significant impact on output; the ability to "see" is heavily dependent on software for manipulation and visualization. These factors are a complex mix of objective parameters (e.g., point density) and subjective judgments that are inextricable from the pervasive issue of archaeological interpretation.

Archaeologists decide which platform to use (aerial, satellite, ALS) and which electromagnetic emission to record. Similarly, data-processing, the selection of suitable algorithms, and their mode of visualization are matters decided by researchers. The final image undergoes visual editing and interpretation according to knowledge and interpretation experience and is accepted when a result is deemed to be satisfactory. Thus, like all other forms of archaeological data, the corpus of aerial photographs is the result of reconciling observation and imagination, of matching what we want to know, what has survived, what we currently recognize, and the methods available for their detection and recording. These methods are improving all the time as fresh interpretations raise our expectations and ambitions further.

Current Trends

The enormous dynamics of modern technological changes in the field of acquisition of remote sensing data and their computer processing have

Aerial Archaeology, Fig. 5 Drone with camera over the archaeological site (Photo: W. Rączkowski, 2013)

influenced the shaping of new trends. On the one hand, these trends are very distant from the traditionally understood aerial photography, and, on the other hand, they do not question its basics, achievements, and identified problems.

Mass introduction of UAVs (Unmanned Aerial Vehicles) have significantly captured imagination of archaeologists. UAVs equipped with GPS devices are a technology which allows in a quick and a cost-efficient way raising a camera/sensor in the air and in a short time getting a picture of archaeological sites/features (Fig. 5). Thanks to the appropriate software from the Image Based Modelling group, a series of photos help to generate detailed 2D orthomosaics and 3D models. Therefore, this technology introduces new elements to the broad practice, which have until now been difficult and expensive although obtainable (photos from model planes, balloons, and kites have been known since the 1920s, and photogrammetry allowed to create orthomosaics). The indubitable advantage of UAVs usage in archeology is ease of use and the ability to reach even hard to reach places. However, generally available technology does not mean common ability to interpret the generated 2D orthomosaics and/or 3D models. This leads to the common situation which is present from the very beginning of the usage of a traditional aerial reconnaissance, when the main objectives were brought to discovering and documenting relics of past human activities (Cowley et al. 2018). Due to technological constraints, UAVs are usually used to document individual sites/features (including excavation works) and have limited capacities when it comes to studying past landscapes.

Traditional aerial reconnaissance is gradually losing its importance although it does not mean its elimination from the field of interest and reflection of archaeologists. Archaeologists conducting an aerial survey are currently equipped with GPS and also have access to the archaeological heritage database. This allows taking many more rational actions in the field of flight route planning and straight line recognition of selected regions, and as well, making decisions regarding the shooting of visible cropmarks/soilmarks/earthworks. Appropriate software allows quick geotagging of the taken photos and their cataloging. Also aerial photographs taken during a traditional reconnaissance can be used to create 2D orthomosaics and/or 3D models.

Aerial Archaeology, Fig. 6 Kaczkowo, Kujawy Region, Poland. The Early Neolithic trapezoidal long houses as seen on satellite imagery (QuickBird 2, 4.07.2005) – panchromatic channel (upper) and channels: NIR, G, B (bottom) (© 2005 DigitalGlobe, Inc. ALL RIGHTS RESERVED)

Satellite technologies are increasingly entering the AA. This involves assembling on satellites such sensors, which allow getting very high ground resolution. The extract of specific technologies of data acquiring is more and more apparent. Currently, optical high-resolution Earth Observation techniques (Lasaponara and Masini 2012) are dominating, but there are also attempts with the use of synthetic-aperture radar (SAR – Stewart 2017). Each of the aforementioned techniques requires different data processing procedures and its interpretation. Currently, optical satellite imageries techniques are more far-reaching due to available high ground resolution (currently even up to 30 cm). Previous experience has shown that the possibilities of archaeological structure identification on optical satellite imageries are related to the same phenomena, which lead to the presence of cropmarks and soilmarks recorded on aerial photographs (Fig. 6). Consequently, all problems associated with the interpretation of aerial photographs are also related to high-resolution optical satellite imageries.

Still, one of the most developed methods is ALS. In the applications, special attention is paid to the use of algorithms, which allow us to emphasize specific aspects ALS derived DTM (e.g., Sky

View Factor, Local Relief Model, Openness, Cumulative visibility) (Kokalj and Hesse 2017). Variety of ways to visualize data in a greater degree highlights the complexity of their interpretation process. The new challenge is to develop a method of generating DTM for coastal zones (hydrographic airborne laser scanning systems – Doneus et al. 2013) allowing identification of submerged archaeological relics.

Technological changes in many fields of aerial photography applications and remote sensing data open the possibilities and the need for systems which allow for creation of total coverage surveys with the usage of aerial photographs, ALS data, or satellite images. As a result, acquiring large amounts of data requires automated and semi-automated tools allowing image correction and their enhancement leading to management and interpretative mapping (e.g., Verhoeven and Sevara 2016).

Undoubtedly, technology opens new possibilities in recording traces of the past and allows constructing new narratives. However, it cannot be forgotten that in studies about the past, data visualization is something other than traditional, analogue aerial photography. Remote sensing users must be aware of the complexity of the process, including data acquisition → data processing → data visualization → interpretation. This is the subject discussed in the community, and it is essential for conscious and critical studies about the past.

Regardless of the interest in new technologies, the community of aerial archaeologists recognizes the value of historic aerial photographs. Historic aerial photographs, mostly from the World War I, but also taken later during World War II and by military spy missions, are an extremely important source of information about relics of past human activities as well as past landscapes. A great deal of interest about this potential can be attributed to numerous conferences devoted to this topic and publications (e.g., Cowley et al. 2010; Hanson and Oltean 2013; Stichelbaut and Cowley 2016). In addition, historical aerial photographs play an important role in the new currents of archaeology (e.g., archaeology of contemporary past, conflict archaeology).

In Europe, the Aerial Archaeology Research Group is a main platform for discussions on archaeological applications of aerial photographs as well as other airborne and satellite remote sensing data (http://www.univie.ac.at/aarg/).

Aesthetics in Archaeology

Thomas Heyd
Department of Philosophy, University of Victoria, Victoria, BC, Canada

Introduction and Definition

The term "aesthetics" was coined in the eighteenth century by Alexander Baumgarten, who thought of it as "the science of sensible cognition" (Baumgarten 1961 [1750–1758]: §1, 107). As such, it concerns the study of how to think the sensible appearance (the look/sound/feel) of things when the focus is on their perceptual qualities. Immanuel Kant further added to this conception by proposing that aesthetic judgment involves a claim *not* based on an (objective) *coming to know* of the world but on a particular (subjective) *feeling* produced in the encounter with objects of perception. The feeling in question is produced when the faculties of imagination and understanding are in "free play" while provoked by various objects of perception (Kant 1790 trans. 1987: Pt. 1, Book 1, Section 9).

Accordingly, aesthetics is concerned with the claim that the *particular way* in which things are present in our awareness may lead to a certain kind of object-related but subjective feeling. Concretely, the feeling in question responds to *the particular disposition* of things, be it the composed *ordering* of sounds; the *layout* of material things in space; the choreographed *pattern* of movement of bodies through three-dimensional space; the *design* of two-dimensional surfaces; the meaningful *arrangement* of words; the determinate *sequencing* of the contents of the imagination based on some written, heard, or visual narration; or some other perceivable *structuring* of our perceptual world, including, for example, diverse forms of "skilled and knowledgeable forms of action" (Pollard 2001, 318).

While Baumgarten and Kant intended aesthetics to address itself to a *very wide* range of objects, later theoreticians tended to focus on *artistic* manifestations, as found in the Western world. This orientation has caused concern among archaeologists and anthropologists about the application of the aesthetic gaze to their objects of study, insofar as it would bring about ethnocentric and anachronistic conclusions, especially since many cultures seem not to distinguish between art and other spheres of life. The worry is that by using the categories of Western aesthetics and art in the study of the archaeological record, epistemological, methodological, as well as ethical problems seem to arise.

Key Issues/Current Debates/Future Directions/Examples

The situation would seem to pose an epistemological problem since, due to limited access in archaeological research to the context of the objects studied, it may be questioned whether we can know that the people, who made and used

these things, in fact had the intention of making them with the types of aesthetic qualities that we value in standard Western artworks of the modern period (Soffer and Conkey 1997). Furthermore, there is the problem of how the disposition or structuring of things may have been appreciated by their makers and users if we have reason to believe that their perceived world differed radically from ours. In other words, their different "perceptual sensibilities" would suggest that their appreciation of things would have been significantly different from ours and, consequently, it may be difficult to know whether anything counted as aesthetically valuable in the first place and, furthermore, in the case that there were such things, which of them and which qualities were actually aesthetically valued.

Methodologically, there is the problem that the focus on aesthetics and art seems to lead down the wrong path because oftentimes *universal validity* has been claimed for aesthetic and art-oriented categories that in fact import perspectives and values of *merely regional and historical validity*, as developed in the artworld of European peoples between the eighteenth and twenty-first centuries (Tomásková 1997; White 2003; Moro Abadía and González-Morales 2008). Ethically, moreover, the utilization of these categories entails the problem that, insofar as they are value-laden, their application to objects from other cultures may lead to inappropriate value judgments (often expressing ethnocentrism) about other peoples' cultural goods (Heyd 2003, 2007; Heyd and Clegg 2005).

However, these respectively epistemological, methodological, and ethical concerns actually arise because of the narrowing down of the object of aesthetics to a very limited, geographically local and historically conditioned, notion of "art." As it happens, aesthetic judgments are also issued in a great variety of *nonartistic* contexts, such as regarding human beings and natural landscapes or even concerning thought constructs such as mathematical formulae. *Anything* may become an object of aesthetic attention when it is considered as the trigger for a particular kind of feeling grounded in the reflexive appreciation of one's perceptual contents (Ziff 1997). Human beings everywhere sing, produce poetry, tell and enact stories, and draw or fashion three-dimensional objects in order to delight and engage their fellows and children. As such, aesthetic judgments are ubiquitous and, as evolutionary aesthetics argues, probably can be projected back to our species' deep past (Davies 2006, 1–25). This situation, in turn, invites closer consideration of aesthetic values in the archaeological record as a topic of research.

While anthropology may be said to have considered aesthetics as a research tool at least since the 1990s (Coote and Shelton 1992; Gell 1992, 1998), interest in theorizing its application in archaeology is more recent. Starting from the perspective that the aesthetic values perceived in things have socially relevant effects, it is argued, for example, that tracking the ways in which such effects are produced may open up an understanding of important aspects of the cultural systems under study (Gosden 2001). From this perspective, the plethora of possibilities for structuring physical objects two- and three-dimensionally, and even their arrangement in space in relation to other objects, may constitute valuable resources for cultural insight (as demonstrated by Pollard 2001, in his study of depositional practice).

One very general argument for the consideration of the aesthetic perspective in archaeology is that many cultural goods, be they material (such as pots, knives, or shoeing) or more notional (such as texts describing religious ideals or social hierarchies), even if produced for practical uses often evidently exhibit *more structuring than necessary* to realize a specific function or to get a particular message across (Dobres 2001). Relevantly, the perceptually accessible structuring of the carriers of information may be accessible to archaeologists as, for example, in the case of humanly made marks on rock commonly referred to as "rock art" (e.g., see Fig. 1).

Aesthetically relevant choices commonly are evident in the making of these markings on rock. Moreover, often it is clear that the sites are chosen among other sites available, that only certain surfaces on those sites are selected even if others could be used, that certain modes of image making (e.g., painting, engraving, stencils, or wax application) are utilized when other modes are

Aesthetics in Archaeology, Fig. 1 *Gwion Gwion*, Kimberleys, Northern Australia. (Taken by Heyd in 2000)

possible, and that motifs perceived may be represented in more or less dynamic, restrained, interactive, or striking ways. The multiple, perceptually significant choices realized in each site suggest empirically testable hypotheses with regard to the significance of the markings for their makers and users.

For example, large images in wide open areas may be understood as directed toward people at a distance, suggesting that they may have group representational functions, while small images only accessible by, or visible to, single individuals may be meant for more private, potentially spiritual, functions. Dazzling figures may be meant to impress friend, foe, or commercial exchange partner (Gell 1992, on the decoration of Trobriand canoe prows, and Morphy 1992, 2005, on Yolngu *bir'yun* brilliance), while hand stencils may be intended as referential to personal identities (Forge 1991, 40).

Insofar as the making of images requires attention to how the marks created appear to onlookers, aesthetic judgments and the application of skill and knowledge would have been required on the part of their makers. Furthermore, insofar as different aesthetic values are generated through the choice of particular formal qualities, the ability among viewers to "read" aesthetically relevant differences would have to be presupposed. Hence, *not* attending to the aesthetics of such images would be to overlook potentially important aspects of the forms of life of the human groups studied (also see Heyd 2012).

While concern regarding the importation of values and categories from the cultural context of the researcher into her or his objects of research certainly is relevant and legitimate, this danger and the ways in which it can be addressed are nothing new within the wider anthropological and archaeological context. Appropriate methodology in this respect would argue for the need to recognize cultural biases and the application of empirical techniques that allow specific cultural differences to *emerge*

from the archaeological text, instead of forcing the given into the procrustean bed of Western aesthetic categories. Certainly, recovering a sense of the aesthetic impact of any structuring of items found in the archaeological record on their makers and users will have to remain at the level of an educated guess. As Gosden (2001, 166) suggests, this requires "an unlearning" of our own sensorium to facilitate the appreciation of the sensory environment that may have existed for those who left material traces in former times. In sum, we may conclude that though aesthetic perspectives in archaeology undoubtedly have played a part throughout archaeological research in the past, its theoretical grounding and systematic exploration are still in development and likely will produce significant payoff in future research endeavors.

African Diaspora Archaeology

Christopher C. Fennell
Department of Anthropology, University of Illinois, Urbana, IL, USA

Introduction and Definition

Archaeological investigations of African diasporas have expanded dramatically in number, diversity of research designs, and geographic

scales over the last several decades. The term "diaspora" is typically used to address the dispersion of people to new locations as a result of hostile circumstances in the areas from which they departed or were abducted. Analysts have pursued a diverse array of perspectives in this period of growth for African diaspora archaeology. Projects have explored questions in spatial scales spanning the household, local, regional, interregional, and global.

Historical Background

Researchers undertaking interdisciplinary studies of African diaspora sites and communities will benefit by familiarity with the analyses of scholars in Black studies, such as Frederick Douglass, St. Claire Drake, W. E. B. Du Bois, bell hooks, Zora Neale Hurston, Arturo Schomburg, Booker T. Washington, George Williams, Carter Woodson, and Malcolm X (e.g., Mullins 2008). The work of investigators of African diaspora communities is also aided by digital and internet-based databases. These include *The Trans-Atlantic Slave Trade: A Database on CD-ROM* (Eltis et al. 2000) and the expanded *Voyages* database available online (Eltis and Halbert 2013), which provides information on 34,948 slave vessel voyages and the people captured in those operations of bondage (e.g., Eltis and Richardson 2008). The *Digital Archaeological Archive of Comparative Slavery*, funded and maintained by the Thomas Jefferson Foundation (2017), presents archaeological data from numerous sites in North America and the Caribbean. Handler and Tuite (2015) and their colleagues maintain a substantial online database of historical images depicting details of the operations of the trans-Atlantic slave trade and its impact on past lives. The African Diaspora Archaeology Network (n.d.) consists of numerous collaborating researchers who promote publications such as a quarterly newsletter and the peer-reviewed *Journal of African Diaspora Archaeology and Heritage* (Taylor and Francis Press).

Key Issues/Current Debates

A remarkable variety of research questions have been addressed over the past several decades, often engaging with theoretical debates on subjects such as social group identity, agency, racism, power, class structures, ethnicity, and self-determination (Ogundiran 2008; Fennell 2011 provide overviews). In North America, the vast majority of archaeology projects related to African diaspora sites are conducted by archaeologists working in cultural resource management (CRM) settings. This tendency reflects the higher frequency with which sites of African diaspora heritage are impacted by disturbance due to new construction projects and resultant analysis through CRM procedures (e.g., Joseph 2004). These CRM archaeology projects contributed significantly to the development of African diaspora archaeology in the United States (e.g., Wheaton et al. 1983).

Some researchers advocate the compilation of detailed, contextual studies addressing dynamics at local and regional scales (e.g., Mullins 2006). Researchers also frequently implement investigative plans shaped in part by the interests of descendant communities (e.g., Agbe-Davies 2007 in Ogundiran and Falola 2007). Other analysts recommend a focus on the facets of racial ideologies and capitalist economies on a worldwide scale (e.g., Orser 1994; Mullins 2008).

This variety of research designs includes a focus on the operations of racial ideologies underlying economic structures (e.g., Orser 2007) and African descendants living and working in industrial settings (e.g., Shackel and Larsen 2000 in Delle et al. 2000). Researchers have also explored the ways in which facets of particular African cultures (such as the Asante, BaKongo, Igbo, and Yoruba) were related to continuing developments of cultural beliefs and practices at diaspora sites (e.g., Ferguson 1992). Many sites have yielded evidence of the material expressions of spirituality by African descendant people (e.g., Fennell 2003). The contours of ethnic group identities and new social networks (e.g., Wilkie 2000a; Ogundiran and Falola 2007 in Ogundiran and Falola 2007) as well as processes of ethnogenesis,

syncretism, and creolization (e.g., Fennell 2007) have been examined in extensive studies.

Our knowledge of African diaspora histories has also been greatly enhanced by studies of mortuary traditions (e.g., McCarthy 2006 in Haviser and MacDonald 2006) and health-care practices (e.g., Cabak et al. 1995). Bioarchaeological investigations similarly provide detailed evidence of past lifeways, individual health conditions, and the impacts of enslavement on the physiologies of Africans and African descendants trapped in bondage (e.g., Mack and Blakey 2004). Diverse studies of diets, culinary practices, and consumer choices provide evidence on multiple time periods and spatial scales (e.g., Wilkie 2000b). Investigators have explored the subject of gender dynamics within African diaspora communities and seek to implement feminist critiques of research designs (e.g., Battle-Baptiste 2011). Extensive studies have examined the degree of impacts of particular African pottery-making and ornament traditions on ceramic production at diaspora sites (e.g., Ferguson 1992; Deetz 1993; Singleton and Bograd 2000 in Delle et al. 2000; Hauser 2007 in Ogundiran and Falola 2007).

Other investigations have concentrated on instances of self-determination, resistance against subjugation, and the creation of "maroon" communities (e.g., Weik 2004; Agorsah 2006 in Haviser and MacDonald 2006). Archaeological studies have focused on such dynamics of communities founded by escaped bonds people called "palenques" in Cuba and "quilombos" in Brazil (e.g., Orser and Funari 2001; La Rosa Corzo 2003). The operations of escape networks combating slavery in North America, often referred to as facets of an "underground railroad," have received increasing attention by archaeologists and landscape analysts as well (e.g., Ginsburg 2007; Delle and Shellenhamer 2008). Studies of spatial distributions and the ways people shaped and perceived the surrounding landscape have traversed scales from the household and yard, to neighboring plantations, to community and region (e.g., Handler and Lange 1978; Delle 1998; Battle-Baptiste 2007 in Ogundiran and Falola 2007; Chan 2007 in Ogundiran and Falola 2007).

International Perspectives

Much of the work in African diaspora archaeology has focused on sites in the Americas and Caribbean. A growing body of work addresses diasporas throughout the Indian Ocean region, Middle East, and portions of Asia (Walz and Brandt 2006 in Haviser and MacDonald 2006; de Jayasuriya Silva and Angenot 2008). In addition, an increasing collection of historical archaeology studies of locations in Africa impacted by the trans-Atlantic slave trade presents excellent potentials for comparative analyses in the future (e.g., Hall 2000; Kelly 2004 in Reid and Lane 2004; Schmidt 2006; Ogundiran and Falola 2007).

Future Directions

This brief survey of research questions and methods in African diaspora archaeology illustrates the remarkable breadth and diversity of the field. Future work provides great promise for comparative and synthetic analyses of sites spanning the Americas, Africa, Europe, and Asia. Rapid advances in bioarchaeological methods, DNA studies, and stable isotope analyses have the potential to provide increasing data on direct connections between populations across space and time. Ongoing developments in spatial modeling, remote sensing, accessibility of aerial and satellite data, and complex mapping programs will also enhance landscape and spatial studies. Researchers in African diaspora archaeology pursue these state-of-the-art advances while also maintaining close ties with the interests and questions advanced by members of African descendant communities.

African Diaspora Archaeology Network (ADAN)

Christopher C. Fennell
Department of Anthropology, University of Illinois, Urbana, IL, USA

Basic Information

The African Diaspora Archaeology Network (ADAN) consists of collaborating scholars, researchers, and interested parties with expertise in African diaspora studies, archaeology, material culture analysis, African histories, and studies of the many developments and changes over time in African diaspora communities. The term "diaspora" typically addresses the dispersion of people to new locations as a result of adverse and hostile circumstances in the areas from which they were abducted or departed. The ADAN (n.d.) describes its mission as connecting "an intellectual community that considers the historical processes of culture, economics, gender, power, and racialization operating within and upon African descendant" populations.

Major Impact

The ADAN includes a quarterly, open-access newsletter published through Internet distribution to thousands of readers worldwide. The network also presents extensive resources for community members and researchers through its Internet site (ADAN n.d.) and often convenes an annual forum at the conference of the Society for Historical Archaeology (SHA).

The ADAN and its quarterly newsletter are successors to the African-American Archaeology Network (AAAN) and newsletter. The AAAN was organized by Theresa Singleton in 1990, and its newsletter was edited and produced in succession by Singleton, Thomas Wheaton, and John McCarthy up through 2000. The ADAN was organized in 2005 by a group of collaborating scholars and adopted a new name to focus on the broader geographic scale of African diaspora communities worldwide.

The field of African diaspora archaeology has witnessed a remarkable expansion in the number of projects, scope of investigations, and variety of research questions pursued over the past several decades. This growth was illustrated in discussions at an ADAN forum entitled "Research Designs for Atlantic Africa and African Diaspora Archaeologies," convened in 2007 at the annual meeting of the SHA. Those forum discussions focused on interpretative frameworks and theoretical constructs utilized in African diaspora archaeology projects. Debates also addressed comparative historical archaeology investigations of sites in Africa impacted by the trans-Atlantic slave trade. The resulting assessments of the state of the field demonstrated that researchers are pursuing a breathtaking variety of research questions. Such analysts address relationships between people, material culture, and historical processes across spatial scales spanning local, regional, interregional, hemispheric, and global frameworks (Fennell 2011). Collaborators from the ADAN also launched the peer-reviewed *Journal of African Diaspora Archaeology and Heritage* (Taylor and Francis Press) in 2012. News, current events, and conference announcements are now disseminated through social media Internet sites (ADAN, News and Events n.d).

African Stone Age

Grant S. McCall and Rebecca Taylor-Perryman
Tulane University, New Orleans, LA, USA

Introduction

The African Stone Age spans the first 2.5 Ma of human prehistory, beginning with the world's earliest stone tool production and continuing through the historical period of European colonization. The African Stone Age includes a tremendous diversity in terms of the characteristics of its industries and the life ways engaged in by its makers. Archaeological research on African stone tool industries has had wide-ranging impacts on our understanding of processes of human evolution and the organization of past human societies.

Definition

The African Stone Age is conventionally divided into three phases, including the Early, Middle, and Later Stone Ages (ESA, MSA, and LSA). The ESA includes the Oldowan, Developed Oldowan, and Acheulean industries. Oldowan industry is thought to have begun with the world's oldest known stone tool technology at the site of Gona, Ethiopia, dating to around 2.5 Ma (Semaw 2000).

The Oldowan industry is characterized by the production of flakes using direct hard-hammer percussion, though bipolar flaking is also known Delagnes and Roche (2005). Common core forms include choppers, discoids, and polyhedrons. Retouched tools mainly include various types of scrapers and denticulates, though flake retouching is not common in most assemblages. The Oldowan gives way to the Acheulean industry between around 1.8 and 1.5 Ma, though this transition appears to have occurred gradually. Numerous securely dated Oldowan sites are known across eastern and southern Africa, and stone tool assemblages with Oldowan characteristics have also been identified in both the eastern and western Sahara (Plummer 2004). It is reasonable to conclude that the Oldowan industry was a pervasive phenomenon across Africa during the Lower Pleistocene.

The earliest known Acheulean assemblages occur at sites dating between around 1.8 and 1.5 Ma in the Konso Formation of Ethiopia (Asfaw et al. 1992), the West Turkana region of Kenya (Roche 2003), and at Olduvai Gorge in Tanzania (Leakey 1971). Acheulean assemblages include the same core and retouched tool forms as the Oldowan but are defined by the production of large bifacial hand axes, which are also referred to as "large cutting tools" (LCTs). Acheulean sites are known from all regions of the African continent. Hand axes at early Acheulean sites were produced through a process of alternate flaking using direct hard-hammer percussion, which resulted in large tools with bifacial edges. Middle Pleistocene Acheulean assemblages show more sophisticated flaking techniques for the purposes of bifacial thinning, including the use of soft-hammer percussion and the preparation of striking platforms (Ambrose 2001). Terminal Acheulean industries, such as the Fauresmith industry of southern Africa, are characterized by the production of much smaller hand axes and the increasing prevalence of other core reduction strategies. The Acheulean industry gives way to the Middle Stone Age between around 300 and 200 ka.

The Developed Oldowan industry is contemporaneous with the early period of the Acheulean industry, ranging in age between 1.8 and 1.0 Ma. It is mainly defined by the absence or scarcity of hand axes, though Developed Oldowan assemblages often include crude bifacial core forms, such as picks (Leakey 1976). Retouched tools also occur in somewhat higher frequencies and with more diversity than in the Oldowan industry. While there is some controversy in the definition and identification of Developed Oldowan sites (Semaw et al. 2009), a number of examples have been documented in eastern and southern Africa as well as in the Sahara.

The earliest known MSA sites are located in the Kapthurin Formation of the Kenyan Rift Valley and date to around 280 ka (Tryon and McBrearty 2002). Elsewhere in eastern and southern Africa, the transition from the Acheulean to the MSA appears to have occurred somewhat later, ending by around 200 ka. The Middle Stone Age is defined by the use of the Levallois technique, in addition to other varieties of centripetal core reduction strategies and the use of striking platform preparation. These core reduction strategies had their origins earlier in the later Acheulean industry, perhaps predating 500 ka (Rolland 1995). In the MSA, however, they comprise a more prevalent element of core reduction strategies and the production of hand axes largely ceases. Thus, the transition from the Acheulean to the MSA may again be described as a relatively gradual shift in the prevalence of various core reduction strategies at the boundary between the Middle and Upper Pleistocene (Tryon et al. 2005: 201).

The MSA is also the first period in which stone points were produced in significant frequencies using both the Levallois technique and through the marginal retouching of flakes. Such points are thought to have served as the tips of hand delivered spears. In addition, the MSA is characterized by low frequencies of other retouched tools, including various types of scrapers, notches, denticulates, and trimmed flakes. The latter MSA, after around 100 ka, is characterized by increasing regional diversity in terms of stone tool traditions. In southern Africa, the distinctive Still Bay and Howiesons Poort industries, respectively, defined by the production of thinned bifacial points and backed blades, appear between 80 and 55 ka

(Henshilwood et al. 2001; McCall 2007). In eastern Africa, the Mumba industry dates between 60 and 50 ka and is also defined by the production of backed blade technologies. In northern Africa, the Aterian industry appears between 80 and 40 ka and is defined by the production of stemmed points and bifacial points (Cremaschi et al. 1998). It is also important to note that these later regional MSA industries are associated with the appearance of the earliest symbolic objects, which have important implications for the origins of modern cognitive, linguistic, and social capabilities (Henshilwood and Marean 2003).

The LSA begins in eastern and southern Africa between 50 and 40 ka and is characterized by the production of small microlithic tools (Wadley 1993; McCall and Thomas 2009). The earliest uncontroversial LSA assemblages are known from the site of Enkapune Ya Muto in Kenya, though putative LSA artifacts predating 40 ka have also been found at the South African site of Border Cave. Elsewhere in southern Africa, MSA traditions have been documented dating to 25 ka or later, demonstrating that the transition from the MSA to the LSA was both a time-transgressive and geographically mosaic phenomenon. While most LSA industries are characterized by microlithic stone tool technologies, this is not universal. For example, the South African Oakhurst industry dates between around 12 and 7 ka and is defined by the production large flakes and the frequent retouching of these into informal scrapers.

In the eastern Sahara, terminal Pleistocene and Holocene microlithic stone tool industries share most formal qualities with the LSA of sub-Saharan Africa but are generally referred to as Neolithic using the Levantine nomenclature system (Wendorf et al. 1976). Across Africa, LSA stone tool industries are associated with origins of pastoralist and eventually allied small-scale agricultural economic systems, occurring first in the Sahara around 9 ka and spreading to sub-Saharan Africa subsequently. The use of stone tools comes to an end with appearance of iron technology, which becomes increasingly prevalent between 2 and 1 ka. In southern Africa, forager and pastoralist populations continued producing stone tools in the Wilton industry of the LSA through the historical period of colonial contact. Isolated cases of stone tools production, such as the manufacture of stone scrapers by hide workers in Ethiopia, have persisted into the twenty-first century.

Historical Background

Early research on the African Stone Age was associated with the expansion of European colonial territories in Africa during the late nineteenth and early twentieth centuries. The three-age Stone Age chronological system was first proposed seriously by the South African archaeologists John Goodwin and Clarence van Riet Lowe (1929), though Goodwin was heavily influenced by his training under Miles Burkitt at Cambridge University. Following from Burkitt (1925), Goodwin and van Riet Lowe (1929) eschewed the three-age system used to classify the European Paleolithic (Lower Paleolithic, Middle Paleolithic, and Upper Paleolithic) in favor of a chronology unique to the African continent. The reason for this revolved around the widely held Eurocentric view that while the African Stone Age sequence showed some similarities with that known from Europe, its industries occurred later in time and were inferior reflections of their European origins. In short, the various stone tool industries found in Africa were thought to have originated earlier in Europe and diffused into Africa, degrading in quality over space and time.

This view was seriously challenged beginning in the late 1950s by the research of Louis and Mary Leakey, who were the first to establish the deep antiquity of Stone Age artifacts in eastern Africa using newly developed isotopic dating methods (Leakey 1971, 1976). Their research showed that Oldowan artifacts dated to at least 1.8 Ma – much older than what had been supposed and also significantly older than any known stone tool technology in Europe. Subsequent research demonstrated that virtually every early stone tool industry known in Europe had its predecessors in Africa, reframing Africa as the location of the origins of both our earliest human ancestors and their technological traditions. Furthermore, the

increasingly synthetic reconstructions of African prehistory in the 1960s produced by archaeologists such as Desmond Clark and Glynn Isaac, as well as their students and colleagues, demonstrated that African Stone Age industries were as complex and sophisticated as any known from other regions of the world.

This trend continued with respect to research on the MSA and modern human origins, thanks in part to further advances in dating technology. While the MSA was once seen as static and underdeveloped relative to European Middle and Upper Paleolithic sequences, it is now known that the MSA was the source of many key behavioral changes among early modern human population. It is now widely acknowledged that many features of the so-called Upper Paleolithic Revolution in fact had their origins in African MSA (McBrearty and Brooks 2000; Henshilwood and Marean 2003). Furthermore, it is increasingly recognized that many important technological features of the Mesolithic and Neolithic microlithic industries of Eurasia originated much earlier in the Upper Pleistocene with the appearance of the LSA in Africa. Thus, the African Stone Age has become a major focus of research on a wide range of global Paleolithic phenomena in terms of the evolution of humans and their expansion across the Old and New Worlds.

Key Issues/Current Debates

The African Stone Age continues to be the subject of a wide range of active archaeological research and debate. Such debates involve issues of prehistory as well as archaeological method and theory. They primarily revolve around accurately reconstructing the life ways of past populations and the complexity of associated social structures, cognitive capabilities, and symbolic practices.

Current research on the ESA has focused on assessing the sophistication of knapping activities and putting these in the context of forms of archaeological information concerning economic and social behaviors. Making use of *chaîne opératoire* and allied methods of lithic analysis, this line of research has demonstrated that even the earliest hominin flintknappers associated with Oldowan lithic assemblages had a solid mechanical understanding of platform angles and other aspects of core geometry – something that even the most highly trained and sophisticated chimpanzee knappers lack (Toth and Schick 2009). Similarly, research on Middle Pleistocene Acheulean assemblages has shown that evident processes of bifacial thinning require a high degree of knapping skill, perhaps implying both sophisticated cognitive and social/linguistic structures for teaching (McPherron 2000). These insights stand in contrast with prior views of early hominin behavior and cognition, which have tended to see ESA archaeological assemblages as indicating much more apelike behavioral patterns.

Archaeological research on the MSA has exploded within the last two decades with profound implications for our understanding of modern human origins. New dating technologies and expanded programs of field research have radically overhauled our knowledge of MSA prehistory and the nature of early modern human cultural behavior. Such discoveries include the world's earliest symbolic objects, ground bone tools, blade-based lithic technology, as well as evidence for other complex knapping procedures and the exploitation of labor-intensive subsistence resources. These behavioral features have been used to define the European "Upper Paleolithic Revolution" and the broader concept of "behavioral modernity" (Mellars 1989; Shea 2011). In addition, research on MSA lithic technology has offered increasing clarity concerning the kinds of technologies, subsistence practices, and mobility systems employed by early humans. Combined, modern research on the MSA has provided important insights concerning the origins of modern humans, their shifting cultural behavior, and their spread to the rest of the world.

By virtue of finer-grained chronological information and historical associations with modern forager groups in the Kalahari and East Africa, research on the LSA has sought to investigate the nature of later prehistoric foraging forms of technology, economic practices, and social systems. Research on rock art, especially in southern Africa, has offered important information

concerning the nature of LSA social structures, religious practices, and cosmological constructs (Lewis-Williams 1983). Recent research has also focused on the transition from foraging to small-scale farming and pastoralist economic systems, as well as the complex forms of interaction between later LSA foragers and their agricultural neighbors. Finally, the transition from the MSA to the LSA is now receiving renewed attention in light of new excavations and improved dating techniques.

International Perspectives

The bulk of early archaeological research on the African Stone Age was conducted under the auspices of European colonial (especially British) academics and their associates in various African colonies. For example, John Goodwin, Louis Leakey, J. Desmond Clark, Glynn Isaac, and Brian Fagan all received graduate education in archaeology at Cambridge University in the early to middle twentieth century. Beginning in the 1960s, an initial generation of African professional archaeologists emerged and populated departments of archaeology at local universities, especially in South Africa. While this generation remained committed to the methodological and theoretical directions that originated in Europe, archaeological research on the African Stone Age began to take on a distinctive regional flavor.

The 1960s also saw the movement of many of the most important African Stone Age archaeologists to major research universities in the United States, such as the hiring of J. Desmond Clark and Glynn Isaac and the University of California Berkeley in 1961 and 1966, respectively. This trend had the effect of fostering the increasing involvement of American archaeologists on African Stone Age topics. Beginning in the 1970s, American archaeologists began to make important contributions on topics ranging from dynamics of lithic reduction, patterns of bone modification, site formation processes, ethnoarchaeology, and experimental archaeology. The increasing popularity of African Stone Age research topics also attracted the attention of powerful foreign scholars, such as Lewis Binford. Within the last two decades, archaeologists from other regions, such as various Western European countries and Australia, have made increasingly important contributions. For example, French Paleolithic scholars, such Anne Delagnes, Pierre-Jean Texier, and Jean-Philippe Rigaud, have offered new perspectives in terms of the application of *chaîne opératoire* approaches to lithic echnology in the ESA and MSA.

Perhaps the most important shift in terms of research on the African Stone Age has been the increasing involvement of indigenous scholars and African governments in the examination and preservation of Stone Age cultural resources. While this has been a continent-wide phenomenon associated with the gaining of independence from European colonial powers, it has been particularly salient in the Rift Valley nations of East Africa (especially Ethiopia, Kenya, and Tanzania) and South Africa. Across Africa, the record of human evolution and cultural diversity associated with the Stone Age has become increasingly recognized as a crucial element of cultural patrimony. With that said, indigenous involvement in research on African Stone Age topics remains regrettably rare (Shepard 2002).

Future Directions

Research on the African Stone Age is in the midst of a significant period of reorientation based on the development of new analytical methods and dating techniques as well as the expansion of available data sets through the proliferation of fieldwork projects.

Research on the Oldowan and Acheulean industries has recently focused on the evaluation of early hominin cognitive capabilities and the complexity of social organization. Future research is poised to make use of a wide range of evidence resulting from human and chimpanzee knapping experiments, further archaeological and ethological investigations of chimpanzee tool use and associated activity areas, and more detailed analysis of archaeological assemblages within a technological framework. In addition, various three-

dimensional scanning technologies now allow for the documentation of the shape of tools such as hand axes in much greater detail. Finally, the field is once again turning its attention to the examination of early hominin technological organization, mobility patterns, and broader dynamics of ecological adaptation.

Recent research on the MSA has offered a great deal of new knowledge concerning the design and function of tools and weapons as well as implications for subsistence activities and economic organization. Likewise, having established the presence of many precocious forms archaeological remains associated with early modern humans, recent research on the MSA has sought to evaluate the nature of novel forms of social organization and their potential causes. While some current scholarship has questioned the utility of the behavioral modernity concept (Shea 2011), a great deal of work continues to be focused on the nature of MSA early modern human cognitive and cultural sophistication (Wadley 2012). Future research will no doubt continue to add detail concerning the nature of MSA life ways while improving our understanding of the relationship between various regional phenomena and shifts over time. For example, while the later MSA sequences of South Africa are known in great detail, their relationship with contemporaneous industries in adjacent regions is not. Likewise, the MSA of East Africa remains a neglected topic relative to the study of ESA technologies in the interest of addressing debates concerning early hominin evolution.

Future research on the LSA seems poised to address a range of issues. While the technological and operational characteristics of MSA tools and weapons are increasingly known in great detail, such information remains lacking for the LSA in spite of links with modern forager groups in Africa. The application of a similar research program would seem to have much to offer. In addition, the transition between the MSA and LSA remains a poorly understood process, especially considering apparent differences between various African regions. New directions in research on the LSA might also choose to focus on the continued production of tools by historical and modern societies. Understanding changes in lithic technology associated with processes of colonization and modernization could offer valuable new perspectives on these profoundly important historical phenomena. Finally, future research on the LSA will continue to show the ways in which LSA life ways were specialized aspects of global processes of post-Pleistocene adaptation rather than being "timeless" elements of foraging societies as was assumed by earlier ethnographers and archaeologists.

African World Heritage Fund (AWHF)

Brad Guadagnin
Department of Archaeology, Flinders University, Adelaide, SA, Australia

Introduction

The African World Heritage Fund (AWHF) addresses a dire need to provide greater protection

for World Heritage sites in Africa. The mission of the African World Heritage Fund is to support the effective conservation and protection of natural and cultural heritage of outstanding universal value in Africa (Herbert n.d.). The fund was established in 2006 as an intergovernmental organization to support the protection of World Heritage sites by providing financial support for training, national inventories of cultural heritage sites, and the conservation and management of heritage properties in Africa (Patchett 2006). The aim is to target local populations of the African countries who have signed the United Nations Educational, Scientific and Cultural Organization (UNESCO) convention and support them to implement active approaches to protect World Heritage sites (Herbert n.d.). The major initial contribution to the Fund was a donation of 20 million rand, the equivalent of US$3.5 million, from South Africa (Patchett 2006).

Current Debates

The African World Heritage Fund addresses two issues that are critical to world heritage in Africa: the low number of sites in this region that is inscribed on UNESCO's World Heritage List and the high costs of maintaining the sites that are inscribed on the World Heritage List. The impact of the fund can be judged by an increase in the number of sites in Africa that are inscribed on the World Heritage List and in the number of countries from the region that have sites inscribed on the list or nominations in process.

According to Varissou (2010), the most important task of the African World Heritage Fund is to increase the number of African sites on the World Heritage List. There is a need to impress the importance of listing sites on the local population and to train authorities and site managers of heritage sites with knowledge on how to apply for inscription on the list. In the space of a year, from 2009 to 2010, the fund helped finance 30 sites to conform to the criteria needed to progress for enlistment. When the African World Heritage Fund was established in 2006, only 65 of the 812 sites inscribed on the World Heritage List were located in sub-Saharan Africa and only 24 of the 40 sub-Saharan African states that had ratified the World Heritage Convention had sites on the World Heritage List (Patchett 2006). By 2013, the World Heritage List had grown to 962 properties (UNESCO 2013). Notable sites from Africa that were inscribed during this period include the Sangha Trinational National Parks, situated in the northwestern Congo Basin, at the intersection of Cameroon, Central African Republic, and Congo; the Ounianga Lakes in Chad; Rabat in Morocco; and the Bassari, Fula, and Bedik cultural landscapes in Senegal (UNESCO 2013).

The African World Heritage Fund provides critical support for State Parties in their efforts to ensure that their World Heritage sites conform to the 1972 World Heritage Convention criteria. There is a significant financial burden involved in ensuring that sites inscribed on the World Heritage List continue to conform to the 1972 World Heritage Convention criteria. The maintenance of World Heritage sites is the responsibility of State Parties. In low-income countries, such as those in Africa and parts of Asia, the burden of maintaining sites on the World Heritage List is particularly onerous. In 2013, the critical nature of the situation was indicated by 16 of the 38 sites on the List of World Heritage in Danger being located in Africa (UNESCO 2013). While some of these sites are in danger due to conflict in the region, such as with the Democratic Republic of the Congo, other sites are in danger due to a lack of trained personnel to protect sites or financial resources to put protection measures in place. The African World Heritage Fund provides both forms of support. To achieve these objectives, the fund requires the implementation of a plan to ensure the sustainability and protection of heritage sites.

The capacity building program established by the African World Heritage Fund addressed a

critical need for trained local personnel. As Leitão (2012: 5) points out, Asia and North Africa were the last regions to experience capacity building programs as part of the World Heritage Capacity Building Project. A significant event in this process was a workshop for North Africa which took place in 2012, held in partnership with the Arab Regional Centre for World Heritage and the National Institute for Heritage in Tunisia. The International Centre for the Study of the Conservation and Restoration of Culture Property (ICCROM) and International Union for Conservation of Nature (IUCN) conduct specialized training on World Heritage and conduct assessments to deal with issues surrounding the topic (Leitão 2012: 6). The first two assessments were at the University College Dublin, Ireland, and at the Brandenburg University of Technology in Cottbus, Germany.

Though it was established only recently, African World Heritage Fund plays a critical role in protecting World Heritage sites in Africa.

Age Estimation

Sue Black
Centre for Anatomy and Human Identification, School of Science and Engineering, University of Dundee, Dundee, Scotland

Introduction

Age can be defined as a simple measure of how long a person or an object has existed. A reliable estimation of the age of a human requires there to be a well-defined and documented event to which the duration of a known passage of time can be ascribed. The thorny question then arises about "when" a human begins to exist. This temporal moment of definition between existence and non-existence can be difficult to fix in relation to the human and generally has three measurable options: the time since fertilization or intrauterine implantation (which have most value for embryological or fetal aging), or, most commonly, the time since birth for those who survive the uterine environment and a safe passage into the outside world.

Key Issues

Clinical practitioners, but especially pediatricians, wish to know the date of fertilization to permit them to calculate the age of an embryo or a fetus and to assess that development is progressing at the predicted and normal pace. However, unless there has been only one sexual event, then this timing is unlikely to be a certainty, and so clinicians often opt to calculate the age of the fetus from a more reliable event – the last menstrual period (LMP). The mother is more likely to recall or at least approximate this date but of course this can also be unreliable as she may genuinely not remember or may choose to falsify the information for personal reasons. Therefore, even in the earliest stages of human development, age estimation can be imprecise; a fact which is often little understood by the expectant mother who, when

given a due date for her baby, is disappointed when that date generally proves to be incorrect. Only some 4–5% of babies arrive on their predicted due date, with approximately 80% arriving in the 2 weeks to either side of that date.

To assign an age to a fetus in utero is generally achieved through ultrasound image measurements of the length of the fetus (crown-rump length), biparietal width of the skull, or length of the long bones, especially those in the lower limb. If the fetus has been miscarried or aborted, then additional measures of weight, head circumference, thorax dimensions, and crown-heel length can be measured. If, however, the remains are skeletonized, then age estimation is normally based on either bone lengths or maturation status of several of the skeletal elements (Cunningham et al. 2016). A fetus can be viable from 23 weeks gestation, but chances of survival are greatly enhanced if it is over 25 weeks. In some contexts, legal abortions of a fetus can be undertaken providing the fetus is less than a prescribed number of weeks of gestation (e.g., in the UK it is less than 24 weeks). Thus, there are two very important forensic questions that can be related to the age of the fetus – (a) was it viable and (b) was the termination legal.

Birth is an eminently definable event in relation to both a time and a specific calendar date. It is perhaps the most important human marker of existence and is celebrated by millions of people as an annual event throughout their entire life. In most western countries, birth is formally recorded through authenticated certification so that "proof" of the date does not rely solely on memory but is supported by verifiable documentation. Indeed, this formal record is so important and desirable that it can carry a high black-market price and may be acquired through fraudulent means. This therefore brings the authenticity of the documented information into some debate, and an understanding that forgeries exist is vital to the realistic acceptance that even documentation may not be relied upon. Many less-developed countries may not record birth dates and therefore have no documented basis upon which to develop a robust certification process. This leads to difficulties when the age of a person is required to be known and there is no formal paperwork to support the believed assumption. Under these circumstances, what is referred to as "chronological age" may be questioned and may require verification for the purposes of border crossings, access to services or legal rights. Government departments, banks, employers, law enforcement agencies, and other legislative authorities require confirmation of the age of the individual with whom they interact, and each can, and frequently does, seek legal recourse to resolve disputes over alleged age assignment (Black et al. 2010). Therefore, the estimation of the age of a person is undeniably of forensic relevance (i.e., pertinent to the courts) irrespective of whether the person is alive or dead. The methodologies and principles followed in both circumstances are very similar.

In the case of a deceased person, an assignment of the age at death is an important component of the biological profile of the individual which can ultimately assist with the identification of the remains in forensic and archaeological investigations. Investigation of a crime is exceptionally difficult in the absence of the identity of the deceased, and indeed investigation of the death is critical for the prosecution of a crime. The biological identity of the deceased is comprised of four principal characteristics – sex, age at death, ancestry, and stature. The personal identity of the deceased can be pursued once these primary characteristics have been attributed. Personal traits of identity may include matching for DNA, fingerprints, dental information, and other, what are deemed to be secondary, indicators of identity including facial appearance. The methods used to estimate age vary little, regardless of whether the deceased is of recent origin or of historical provenance.

Age estimation processes are based on the principle that as time passes (i.e., the further one progresses from the date of birth), then a series of biological maturational events will occur that can be mapped out and cross-referenced to the known occurrence and timing of such events. This requires there to be a strong relationship and correlation between two age-related continua: chronological and biological age. The closer biological age is to chronological age, then the

greater will be the accuracy of prediction of one from the other, but the more they diverge, then the more uncertain will be the estimation of chronological age and this will necessitate the provision of a range for the possible age of the individual. The methods utilized in this process tend to show a close and strong relationship between the two ages during childhood, and they start to diverge markedly as adulthood approaches and then move even further apart as middle age approaches and are most divergent into the later decades of human life expectancy. Therefore, the techniques available to forensic anthropologists and osteoarchaeologists permit high levels of accuracy at predicting the age of a child (living or dead), and they are reliable in the later teenage years, acceptable in the early adult years, and very poor in the middle to later years of adult life (Latham and Finnegan 2010).

Biological age has two components, skeletal age and dental age, and each can be established independently or considered in parallel. Skeletal age utilizes information on the timing of formation of bones, their growth, and the pattern of their ultimate fusion to form the final adult product. Almost all growth has ceased in the human skeleton by 30 years of age, and the changes thereafter are degenerative. These are less reliable markers of the passage of time as they are heavily influenced by many factors including genetics, environment, health, nutrition, and life-style. To visualize the skeleton in the living requires that the person usually be exposed to ionizing radiation for imaging purposes (X-ray or computed tomography (CT) scans) although magnetic resonance imaging (MRI) and ultrasound (US) do not carry the same health risks. In the deceased, exposure to radiation for imaging purposes is not as restrictive, and indeed to gain access to the skeleton, soft tissue can be removed through maceration, although of course this does not pose a problem if the remains are partially or completely skeletonized. Age can be estimated to some degree from almost every part of the human skeleton, but obviously in the living, the areas that can be targeted by clinical imaging are restricted and tend to focus on the wrist and, if possible, the medial ends of the clavicle. The radiographic image of the wrist and hand region provides access to at least 29 separate bones, and therefore age estimation can be considered from birth through to middle adolescence with some degree of reliability (Black et al. 2010). Imaging of the medial clavicle permits an indication of age from later teenage years through to early adulthood, but it does carry some health and safety risks in relation to exposure to radiation for imaging purposes. Textbooks exist on how to establish the age of an individual when living (Black et al. 2010), for forensic purposes (Latham and Finnegan 2010) and in the archaeological arena (White and Folkens 2005), but in reality, they all use similar methodologies.

Dental age is predicated on the pattern of known development, eruption, and shedding of teeth that occurs throughout the life of the child (Blenkin 2009). The first tooth to start to develop does so in early embryonic life and the last tooth to reach occlusion does so in early adult life – therefore, accurate age estimation from the teeth is valid from fetal age through to adulthood, but beyond the eruption of the third molars, teeth become less reliable indicators of age (Aka et al. 2016). In the living, teeth are the only hard structures of the body that are visible to the naked eye, and their ability to survive trauma makes them an ideal medium for age evaluation. There is also a largely unsubstantiated, but generally accepted, maxim that dental age is more closely related to chronological age than is skeletal age as the teeth tend to be more protected from environmental insult and so retain a closer parallel progression of the two continua. Therefore, combining estimations of age from the skeleton with those from the teeth will most likely result in an acceptably reliable indicator of age both for the living and the deceased that will be closer to the chronological age than if either were to be used in isolation.

Future Directions

Our modern society demands confirmation of how long we have existed, and the scientist does their best to oblige, but it is never, and can never be, a precise operation. This is the area of research that

is most likely to be prevalent in future years as our security-conscious world focuses on who we think we are, who we say we are, and how we can prove it.

Agency in Archaeological Theory

Marcia-Anne Dobres
Department of Anthropology, University of Maine, Orono, ME, USA

Introduction

Agency is an explicitly humanistic perspective for understanding ancient people and social reproduction. It emphasizes the reciprocal relationship between people's conscious and unintended actions and their social, ideological, and material conditions. Agency is an attempt to bridge three long-standing paradigmatic divides: between theories focused on egocentric individuals "in" society, those concerned with the deterministic nature of normative culture, and theories emphasizing the influence of external (material) conditions on both individuals and society.

After more than three decades of experimentation and critical reflection, there is still little consensus across paradigmatic boundaries as to precisely what agency is (Dobres and Robb 2000, for attempts at a comprehensive definition, see Johnson 1989; Bell 1992; Pauketat 2001; Dornan 2002). Nonetheless, as a conceptual framework and an analytic tool, the utility of agency for making sense of the past is undisputed. And given the heterogeneous interests of twenty-first-century archaeology, perhaps resistance to being pigeonholed by a single set of tenets is part of its wide appeal and its efficacy. For example, recent agency research published across a wide spectrum of archaeological journals, books, dissertations, and edited compendia shows that how agency played out in particular ancient settings varied considerably (e.g., the agentive processes involved in early state formation in Ancient Mexico, Venezuela, and Crete did not unfold in the same manner).

Another aspect of its popularity in archaeology is that the dynamics of agency have shown themselves amenable to empirical investigation. Indeed, practically every kind of archaeological material has been the means to study agency, including post holes, stone tools, trash, monumental stelae, cave art, village layouts, burial mounds, and graves as well as classic material signifiers of technology, economics, prestige, culture contact, and state formation. Methodologically, this is important, because while archaeologists do not "dig up" agency (see below), they can study "it" in any time period, in any place in the world, from practically any paradigmatic standpoint, and using practically any categories of material culture.

The previous three points help explain the appeal of agency across the discipline: (1) lack

of definitional consensus allows the concept to be utilized creatively; (2) agency "looks" different in different cultural, historical, and material circumstances; and (3) research on agency is not limited to only certain times, places, processes, or categories of data.

Nonetheless, agency in archaeology has, at times, been employed far too uncritically (e.g., conflating agency with physical actions or all-knowing and self-strategizing individuals). Uncritical use of the concept remains an epistemological, interpretive, and methodological issue that this presentation cannot hope to resolve.

Definition

Agency is notorious for resisting a single clear-cut definition (Dobres and Robb 2000). Not only do archaeologists employ the concept in numerous and sometimes competing ways, but the "thing" itself is a slippery dynamic that plays out different in different settings. While an early and seminal definition of agency (in sociology) defined it as the capacity to make a difference through action (Giddens 1984; see below), this definition is too narrow to capture the many layers of what agency means in contemporary archaeology.

For example, depending on who you read agency in archaeology has been defined in terms of the rational individual, the conscious (or unconscious) negotiation of intersubjective personhood, free will and intentional (self- or group-serving) strategizing, the normative collective and its construction of reality, conscious or (unconscious) resistance to social norms, adept social practice, unintended goofs and their consequences, and the interplay of individuals, structures, events, and history.

At its core, agency in archaeology is concerned to understand the dynamic relationship between the knowledgeable routines of everyday practice and the ability of agents (both individuals and collectives) to act within and upon larger "structures." In this regard, one major tenet agreed upon by most is that although agents are necessarily conditioned by historical, social, and material circumstances, they are not wholly circumscribed by them.

More specifically, agency is about the unfolding and recursive process of social reproduction. It is about individual and collective agents acting in relation (1) to each other; (2) to their cultural norms; (3) to history; (4) to environmental, (5) material, (6) political, and (7) economic conditions; and (8) in relation to a host of local circumstances. Collectively, numbers 2–8 are called "structures." While structures are necessarily of their own making, agents do not fully control them.

In agency theory, the unintended consequences of habitual (largely unconscious) routines loom large in mediating the reciprocity between agents and their structures. For example, while socioeconomic, political, material, and ideological structures are the resources agents use (imperfectly) to make sense of and act in the world, such structures simultaneously shape how agents think and act. Thus, rather like the chicken and the egg dilemma, the question of agency is not about "which came first (agents or structures)?" but about how, in specific settings, they interacted with and shaped one other.

In sum, agency in archaeology is, at one and the same time, a cultural process, a theoretical concept, an interpretive paradigm, and an analytic tool for making sense of the past in terms of an inseparable suite of dynamics. For its advocates, agency is a corrective bridging the inadequacies and limitations of better-established (albeit more narrowly conceived) processual and post-processual approaches to the past. But to others, the acknowledged difficulty with providing a clear-cut definition acceptable to all makes agency a "platitude" more than a "paradigm" (Dobres and Robb 2000: 3).

Historical Background

The initial inspiration for agency in archaeology (and the social sciences more generally) stems from Marx's famous dictum that "men [sic] make their own history, but they do not make it just as they please; they do not make it under

circumstances chosen by themselves, but under circumstances directly encountered, given and transmitted from the past" (Marx 1969: 15 [orig. 1869]). The more immediate and palpable influence on archaeology begins in the 1980s, with Anthony Giddens' (1984) work on "structuration" and Pierre Bourdieu's (1977) emphasis on habitus and *praxis* (Ortner 1984). The key points of their ideas, as relevant to archaeology, are summarized below.

Giddens' theory, known as "structuration," seeks to understand how society, social rules, and large-scale structures (specifically, sociopolitical and economic institutions and class ideologies) come to exist outside of the agents who make them possible in the first place. Structuration wants to explain how society's structures are susceptible to change if the agents who create and sustain them have little awareness or control of what's going on. Giddens' "duality of structure," in particular, emphasizes how everyday actions create the normative rules and top-down conditions which recursively act back on their creators in a never-ending "dialectic." Structuration theory takes the question of social change seriously because agents and structures do not exist in a homeostatic feedback loop adapting to each other and the "real" world. Rather, agency and structures are processes of interaction, and their relationship is a dynamic dance in which "external" and objectified conditions (viz., structures) are both the architecture and the resources agents use to live in a world of both social perception and material realties. Importantly, it is in this unstable cauldron of agency and structures that change unfolds.

On the other hand, Bourdieu was particularly concerned to counter structuralist notions that agents are little more than robots unconsciously following deep-seated rules and a cultural logic of which they are unaware and impotent to change. Bourdieu's so-called "theory of practice" highlights habitus, which is defined as tacitly learned social practices and routines of action that serve as the resources with which agents cope with their social, ideological, and material conditions (no matter how imperfectly understood). Habitus and everyday practice (*praxis*) are not only normative strategies to get through the day. As an embodied and meaningful form of knowledge of how to get by in the world, habitus is susceptible to both conscious and unintended alteration. Thus, subtle changes in everyday routines, whether by mistake or by intention, can accumulate to change the structures (i.e., the culture) within which they take place.

Importantly, both Giddens and Bourdieu emphasize that the structures "within which" agency unfolds (i.e., institutions of power, history, social rules, traditional and innovative practices, as well as and knowledge) are neither rigid nor do they exist "out there" and in opposition to agents. But because structures are the means by which agents understand who they are and how the world should work, they are perceived as objective (external) entities.

To summarize, agency theory in the social sciences emphasizes habitus, *praxis*, and structures as different but inseparable aspects of social reproduction. Combined, they not only shape how agency unfolds but also serve as the raw material used to act in the world as agents see fit.

In archaeology, agency is thus premised on the idea that both the structuration process and the habitus of everyday practice are relational and recursive dynamics. Structuration and habitus highlight not only the interplay, or duality, of people and society but also their social, ideological, historical, and material conditions – none of which should be teased apart for heuristic (analytic) ease. In this web of life, past and present, neither structures nor agents can exist without the other, neither wholly determines nor is influenced by the other, and change is built in to the very essence of everyday routinized actions (rather than only through conscious political upheaval, culture contact, or change in the environment).

The question of agency entered archaeological discourse as part of the "post-processual" movement (e.g., Johnson 1989; Bell 1992; Barrett 1994) but is currently investigated by researchers of every paradigmatic stripe (not that they all define agency in the same way; see above). Agency was initially a balm to the impersonal and deterministic nature of the functionalist and

systemic (New Archaeology/Processual) paradigm, which gave more credit to the environment and "needs of the system" than to living breathing people. Thus, the attractiveness of agency was, at first, to "find people" (Robb 2010; but see below for new intellectual trends). A parallel interest in agency can be traced, at much the same time, to frustration with how mainstream paradigms discounted the role of gender, in particular, as (1) a form of everyday practice, (2) as a structure and set of rules shaping actions and perceptions, and (3) as a potential source of wholesale culture change (e.g., Dobres 1995).

For archaeologists, habitus and *praxis* are attractive concepts because we dig up palimpsests of everyday material activities and evidence of culture change at numerous analytic scales (Barrett 2001). Similarly, the structuration process is intuitively familiar because archaeological applications of systems theory have already made familiar the idea that archaeologists can excavate a "system" from the patterning of archaeological remains. But on these two points, there are substantive differences, explicated below (see also Dobres and Robb 2005).

Key Issues/Current Debates

Agency and Projects

While archaeologists dig up the material remains of past activities, those activities are not, conceptually, the same as "projects" (Robb 2010). Projects is a concept better suited to researching the dynamics of the agency/structuration dialectic because agency is about more than just doing something with material culture.

For example, the earliest writing projects were more than just activities. As scribal projects, they wove together the agencies of traders and accountants with scribal communities and elite patrons. Epigraphy on a gravestone or on the walls of a chiefly tomb intimately connected the agencies of dead and the living with the agency of the material being inscribed (see below). Accounting projects concerned not only the herds or cloth being counted and the containers of wine and grain being sealed. Each of these was, in turn, connected with the bone, ivory and clay being used for seals, with the chisels used on stelae, and with the technical recopies for ink and papyrus. Thus, more than activities leaving material traces, early writing projects were overlapping fields of social, symbolic, political, economic, and material agency contextualized within structures too numerous to elaborate here (but see papers in Englehardt 2013).

The Agency of Material Things

Extending the idea of agency beyond the original duality of agents and structures, archaeologists now study the agency of material things (Gosden and Marshall 1999; Gosden 2005). In this formulation the material world is not passive, waiting to be brought to life through the physical activities of people. Rather, the material world of objects and raw materials has its own kind(s) of agency that during the unfolding of agentive projects interacts with and thus in part shapes how agents understand the world and act in it.

But material things are not agentive simply because humans give them meanings, values, and functions. From an agency perspective, things are partners in social life and can contribute to or intervene in the best-laid plans of sentient agents. For example, in crafting and using Ice Age sewing needles, bone and stone (burins) collaborated with, but also occasionally resisted, the wishes, skillful gestures, and know-how of the technicians engaging in those projects. In this sense, the agency of bone and stone not only contributed to the "inalienable" value of bone sewing needles but also helped "make" their makers (Dobres 1995).

Agency and Personhood

As mentioned above, the initial focus on agency in archaeology was to humanize the past through explicit concern with human beings and their meaningful experiences in a material world of sociopolitical, economic, and historical structures. Many archaeologists remain focused on understanding how the mindfully, materially, and socially constituted bodies of agents worked in and through their world to give it meaning and shape. This research often appeals to

phenomenology and its attention to how the corporeal senses of embodied experience become both a locus of meaning making and a medium of agency.

As but one example of the (inter)agency of people, communities, structures, projects, and things, Dobres (2000) has explored how an embodied and corporeal sense of (gendered) personhood was negotiated, tacitly, during the most mundane and habitual projects of artifact manufacture, use, and repair during the Magdalenian (Late Ice Age) in the French Pyrénées. Asking about the agency of Magdalenian personhood led to an empirically grounded exploration of the interrelationship between gestural skill, esoteric and practical knowledge, and normative rules about the right and wrong ways to make and use objects in particular material settings. In turn, this concern with personhood led to an appreciation of the materiality and agency of antler, bone, and ivory as well as the artifacts made from them – as agents in their own right.

Agency and Social Reproduction

Clearly, the resources agents make use to act in the world, and the meanings attached to them come about through the routinized practice and physicality of everyday projects. At the same time, such routines are in a dialectical dance with larger-scale structures (such as tradition and history, politics, and ideologies and of course material conditions). Combined, local practice and large-scale structures constitute the "stuff" of social reproduction. But agents employ an imperfect understanding of their circumstances, and they do so with only partial success and with a host of unintended consequences. Thus, from an agency perspective, social reproduction unfolds through a series of relationships negotiated between (1) the agencies of individuals and communities, (2) the agency of material culture, and (3) between these myriad projects and larger-scale historical traditions and structures.

For example, at Umbro and Penitenzeria (Bova Marina, Calabria), Robb (2007, 2010) has used the lens of agency to consider prosaic projects as social and material forms of agency. Foodways, herding, clay and stone technologies, house construction, burials, and trade – these were overlapping projects (not activities) connecting people to their kin, to their ancestors, and to extrafamilial relationships. But more than the stuff of everyday life and habitus, these projects also reproduced the Italian Neolithic writ large. Robb shows how six items of everyday trash are more than traces of an "economic system." The projects in which they were caught up connected them to social actors, to other objects, to symbolic power, to the social landscape, to fields of memory, as well as and to household rites. Thus, social reproduction during the Italian Neolithic was a partnership interconnecting artifacts, agents, habitus, community, and the social landscape with the *longue durée* of history, memory, economic institutions, space, and the environment.

As well, the question of agency has led to new considerations of power and even the question of wholesale culture change. To generalize, the methodological individualism underwriting "rational actor" models holds that humans have a universal desire for prestige and power and will seize the opportunity, consciously, whenever possible. In stark contrast, from an agency perspective the development of sociopolitical and economic inequality is posed as a historically specific and local question of intersubjectivities and contingencies. While some archaeologists investigate how collective expressions of agency made use of older (normative) socioeconomic and political structures in order to reconfigure them in new and unequal ways, others research how traditional ideologies, habitus, and sociomaterial conditions served as a pool of (imperfectly understood) resources with which communities sometimes resisted and sometimes acquiesced to attempts at altering power relationships.

Agency and Scale

As can be seen above, still another way to think about agency in archaeology is in terms of scale. For some, agency is a way to highlight the local, the historical, and the situatedness of "individuals" or intimate collectivities within larger-scale structures beyond their ken. But for others, the interest is on those larger-scale structures. Importantly, when one shifts from the question of small

("micro")- to larger ("macro")- scale concerns, it does not mean that localized expressions of agency are no longer relevant. Because in the past agency unfolded at each and every scale one can identify, research focused on any particular scale must be concerned with the overlapping and possibly contested nature of agency at multiple scales.

Thus, the focus on understanding the agency of people and communities in relation to their social, material, and ideological conditions ranges from making sense of the projects and habitual practices of recognizable individuals to the more anthropological concept of "the individual," to communities of agents (who may or may not have been acting in concert), and all the way "up" to the scale of structures far beyond the control of anyone. Similarly, agency can be studied through the remains of a hearth, a single house floor, a village, a trade route, or an empire – because agency unfolded within and through them all.

International Perspectives

In a brief amount of time, agency has become a popular topic in archaeological research across the globe, and increasingly, such work is being pursued by non-Western trained archaeologists. For example, agency has been used to study the origins of writing in Greece, pottery manufacture in Cameroon, culture contact in Hawaii, lithic production in prehistoric Pakistan, identity in Ancient Egypt, and dynastic-period Chinese burials. As a result, expressions of agency are being identified that do not conform to Western notions, such as the agency of the "we" (rather than the "me"). Indeed, across the globe the current state of research on agency in the past may best be characterized as the study of agencies in archaeologies.

Perhaps the most difficult issue facing archaeologists interested in agency is to learn how to "see" and appreciate expressions that were different from those evident in the modern (capitalist) world (e.g., papers in Knappett and Malafouris 2008). It has been far too easy to succumb to the "me, myself, and I" notion of the egocentric individual and describe past expressions of agency in terms of all-knowing individuals (or agenda-driven groups) consciously manipulating the world to suit their fancy. In this regard, international perspectives on agency are a welcome challenge to Western and capitalist descriptions of the past. It is hoped that international perspectives, framed by non-Western theoretical perspectives, will enable us to ask if we can hope to understand, on their own terms, how differently constituted agentive projects unfolded in settings unlike anything known in the present.

These are among the vexing dilemmas research on agency is only beginning to grapple with, and they will be well-served by increasing input from non-Western trained archaeologists and those studying times and settings wholly unlike the present.

Future Directions

What is both vindicating, but at the same time problematic, is that agency has become a ubiquitous part of twenty-first-century archaeological discourse. It is currently employed by Darwinian, evolutionary, and behavioral archaeologists, by processualists and those favoring ecological perspectives, by feminist and Marxist archaeologists, and by post-processualists of every stripe. Nonetheless, there is still much room for analytical, interpretive, methodological, and epistemological introspection and growth. In archaeology, particularly, many issues still need to be explored and elaborated, among them:

- A phenomenological concern with how normative structures become internalized through the situated subjectivity of everyday practice should be leading us to ask: how did non-discursive and tacit forms of agency play out at collective and larger (macro) scales?
- In different times, places, and in cultural settings, archaeologists could be asking: what, precisely, was the nature of the relationship between embodied and mindful human agents

and their externalized social, political, and material conditions?

- For all the focus on the dialectic of agents and structures, archaeologists still tend to take for granted the question of "tradition" and cultural conservatism. Thus, perhaps it is time to ask: how did agency contribute to long-term social stability?
- On the flip side, more work needs to be done on understanding how microscalar forms of agency, played out in local arenas of materiality and meaning making, contributed to wholesale structural change. Among the topics we might explore from this perspective: how did local expressions of agency and habitus contribute to state formation or the development of agriculture?
- Archaeologists with even a passing familiarity with ethnography are well aware that Western notions of agency, "the individual," and personhood depend on a problematic definition inappropriate for much of the past. Though this does help explain why there is growing interest in the agency of material things, we need to keep asking: what other forms of personhood and agency existed in the past?
- More particularly, how can archaeologists conceptualize, much less study, the agency of class, power, gender, ethnicity, or race? Will a one-size-fit-all (Western-centric) theory and methodology work for all these dynamics? Surely not.

Conclusions

While archaeology is all the better for the inclusion of agency in the study of the past, major epistemological, analytical, and interpretive issues remain unresolved (Dobres and Robb 2005). But there is no doubt that as an explicitly humanistic perspective for understanding ancient people and social reproduction in terms of practice, projects, and materiality, agency is a theoretical concept, an interpretive paradigm, and an analytic tool amenable to studying any time, place, and circumstance of interest to archaeologists.

Agnew, Neville

Neville Agnew
Getty Conservation Institute, Los Angeles, CA, USA

Basic Biographical Information

Neville Agnew joined the Getty Conservation Institute (GCI) in Los Angeles in January 1988. He came to the Getty from the Queensland Museum, Australia, where he had headed the conservation department, which he was instrumental in establishing when he joined that institution in 1980. Prior to 1980, he had pursued a career in academic and research chemistry in South Africa and Australia. Educated in South Africa, he did graduate research in England and received a doctorate in chemistry in 1967. His conservation work in Australia was mainly on the preservation of outdoor sites, including fossil footprints (the Lark Quarry dinosaur stampede site), a maritime archaeological site (the British warship *Pandora* wrecked in 1791 on the Barrier Reef), and the ruins of a nineteenth-century settlement (the penal colony on the island of St. Helena in Moreton Bay). Among his research activities have been a joint Getty Conservation Institute/New Mexico State Monuments project on adobe preservation, development of techniques for preservation and protection of archaeological sites, and a collaborative project with the U.S. National Park Service at Chaco Canyon, New Mexico.

Dr. Agnew has led and participated in many of the international conservation projects of the institute, notably in China where he has worked continuously since 1989, under the Getty's agreement with China's State Administration of Cultural Heritage, at the Mogao ancient Buddhist grotto site and the Chengde Imperial Summer Resort; and among others, in Egypt on conservation of the wall paintings in Nefertari's tomb and the Great Sphinx at Giza; in Africa on the conservation of the bas-reliefs of the royal Palaces of Abomey and the Laetoli hominid trackway in Tanzania; South America in the Quito historic center; and in the city of Prague on the St. Vitus mosaic project. His long association with heritage conservation in China has resulted in a number of awards: the Friendship Award of the State Council in 2000, the International Scientific and Technological Cooperation Award of the PRC in 2005, and awards from Gansu Province and the Dunhuang Academy. He was instrumental in drawing up national guidelines for the conservation of heritage sites in China. Currently he leads the Getty's collaborative projects in Egypt for the conservation of the Valley of the Queens and Tutankhamen's tomb and the Southern African Rock Art Project.

Dr. Agnew has authored publications in research chemistry and conservation, including the book: *Cave Temples of Mogao* (with two coauthors), and is a member of several professional associations, including being on the editorial boards of the journals *Conservation and Management of Archaeological Sites* and *Historic Environment*. For 8 years, he was a board member of the National Center for Preservation Technology and Training (a program of the U.S. National Park Service) and served as chair. He has organized major international conferences and edited the proceedings. These include two conferences at the Mogao Grottoes of Dunhuang and the conservation theme at the 5th World Archaeological Congress held in Washington, D.C., in 2003.

Dr. Agnew is currently senior principal project specialist in the Field Projects department of the GCI.

Major Accomplishments

Neville Agnew has successfully sustained significant multiyear international heritage conservation projects in a wide range of cultures and climates. These collaborative projects, as part of the GCI's international outreach, are premised on identifying significant conservation needs or problems and developing partnerships and teams to address the issues. This has required both conceptual understanding and technical knowledge and the ability to lead. Examples of these projects have been the development of the *Principles for the Conservation of Heritage Sites in China* with the State Administration of Cultural Heritage and the Australian Heritage Commission, technical preservation interventions at the Mogao Grottoes, and completion of a decade-long project for conservation of the earth-based wall paintings at this World Heritage Site. Also at the Mogao Grottoes, the *China Principles* were used in drawing up a master plan which in turn led to the development of a systematic methodology for sustainable visitation to the site. In southern Africa, annual workshops have been mounted for conservation and management of rock art. These have been attended by participants from all 12 southern African countries, and linkages are now being forged with traditional owners of rock art sites in Australia.

In Tanzania, the 6-year project for the conservation of the 3.5-million-year-old Laetoli trackway was completed with educational outreach to local and international audiences. Currently in Egypt, in collaboration with the Supreme Council of Antiquities, a comprehensive plan for conservation and management of the Valley of the Queens with its 100 tombs has been completed, while research and study of the tomb of Tutankhamen is well advanced, in preparation for conservation of the wall paintings and presentation and interpretation of the tomb.

Agora in the Greek World

Astrid Lindenlauf
Department of Classical and Near Eastern Archaeology, Bryn Mawr College, Bryn Mawr, PA, USA

Introduction

The word "agora" derives from the ancient Greek term ageirein, meaning "to gather together" and is attested as early as the eighth century BCE. It is commonly translated as "assembly," "assembly place," and "market place." The agora was a crucial component of all Greek villages and towns across the Mediterranean. According to Herodotus (1.153), the Persian king Cyrus II conceived of the agora as the single most defining characteristic of an urban settlement. For Homer (*Od*. 9.112-5), the agora was not only a constituent part of an urban environment but also signified a form of order and civilization, since he characterized a community without one, such as that of the Cyclopes, as lawless (*Od*. 9.106). The emergence of the agora has been linked with the birth of the Greek polis (city-state). Antonaccio (1997: 170–80) regards the agora, alongside other features including monumental temples and the council house, as an indicator for urbanization. Civic requirements – political, social, commercial, religious, and cultural – were fulfilled in this public place. It was also a place for public display, with honorific statues for good citizens and benefactors as well as political monuments that often functioned to define the collective identity of the polis. Some of these activities and functions were so closely linked to this space that they came to describe it as well as the term "agora," including *choros* (dance), *agon* (athletic contest), and *ekklesia* (popular assembly) (Kenzler 1999: 306). It was originally an open place, but it soon became home to buildings of civic and sacred importance, in line with the growing need to permanently reserve specific areas for specific activities. However, there was nothing that one might call an archetypical Greek agora. While most examples are attested in urban centers, there were also areas designated as agoras outside of settlements (Strab. 9.1.10) and temporary agoras outside of cities, especially in wartime (Thuc. 1.62.1).

Definition

The earliest references to the *agora* can be found in the *Iliad* and the *Odyssey*. While the exact date of the composition of the epics of Homer is debated, most scholars seem to agree that they were written down in the later eighth or early seventh centuries. For Homer and his audience, *agora* could refer to an actual gathering (*Il*. 7.345; *Od*. 9.112, see also Alcaeus F 130b.1-4; Campbell 2002) or an assembly place (*Il*. 18.497; *Od*. 7.44). Once the Greek polis and its rules for communal living were fully developed in the Archaic period, it came to denote a public space that served as the civic and commercial heart of the Greek city-state. This area was sacred in a similar manner to other elements of the urban infrastructure (Martin 1951: 164–201). It served as the locus of governmental proceedings, archives, religious rites, athletic and dramatic competitions, military activities, trading and shopping, philosophical discussions and chats, and eating and drinking.

Historical Background

Both textual and archaeological sources provide evidence for the ancient Greek agora. The earliest use of the word is attested in the Homeric epics, where the word is mostly employed in the sense of a gathering of people and a council assembly (*Il*. 2.143-4; *Od*. 2.26) but also as a topographical term (*Il*. 18.274; *Od*. 2.7). It is occasionally unclear whether Homer refers to the agora as an institution or a location (*Il*. 2.93; *Od*. 10.114). The agora plays a significant role in the world that he created in his poems, but it is much debated to what extent the *Iliad* and the *Odyssey* actually portray Greek society in the eighth century BCE; it is, therefore, better to discuss the Homeric world separately. People in the Homeric world come to the agora to attend court sessions, games, and

assemblies and to watch dances and athletic contests (Kenzler 1999: 304–6). The agora might also be associated with craftsmen, if indeed the shipyards beside the Phaeacian agora provided ship maintenance services (*Od*. 6.268-9). Especially in the *Iliad* (2.48-83), it is also a place where military matters are addressed. In Homeric Ithaca, the men congregate every morning at the agora to talk and gossip (*Od*. 17.52-72); political meetings usually seem to require the presence of their leader (*Od*. 2.26-7, but 2.6-7). In wartime, gatherings could take place close to ships or on the battlefield (*Il*. 1.305; 8.489-92). The agora is an open, sacred space with few structures, located at the temple of Poseidon in the harbor area on Scheria (*Od*. 6.263-7), or in the lower city, below the acropolis (Kolb 1981: 2–3); assemblies could also be held at other places, such as in the citadel of Troy (*Il*. 7.345). The single most important installation is the *hieros kyklos* (sacred circle); the circle of honorary seats (*thokoi*) marked this place permanently (Kenzler 1999: 53–9, 243–8). In the trial scene depicted on Achilles' shield (*Il*. 18.497-508), the elder noblemen sat on polished stones within this circle while the other men of the community gather around them in the open space. Heralds gave staves to the elders who wished to give judgment. Other authors had different names for this sacred circle, and it was called the "orchestra" in Athens (Plato *Ap*. 26d-e), implying that it served for theater performances and other religious activities. The Spartans termed it according to Pausanias (3.11.9) "choros" (dance), suggesting that it functioned as a dance floor.

The agora plays a crucial role in communal life both in the Homeric world and in ancient Greece. While community matters were openly debated in the epics of Homer, court sessions were held by a small number of representatives and followed by an audience that participated through verbal assent (Kenzler 1999: 304–5). In this sense, the agora was an important place for the strengthening of a community's sense of unity. This basic function was not restricted to the Homeric world. In fact, this never changed even if access to the agora and the relative roles of the worlds of the living and the dead within it were subject to change. It appears that access to this public place was unrestricted in Homeric society though not everybody seems to have had the right or power to decide matters of controversy. Many historical poleis, by contrast, clearly defined the space of the agora by boundary markers (*horoi*) and lustral basins (*perirrhanteria*) set up at its edges, and some excluded by law individuals accused of pollution, such as murderers (Dem. 20.158). Assemblies were occasionally held at hero tombs within Homeric society (*Il*. 10.414-5, cf. Kenzler 1999: 307). The relationship between the living and the dead became more permanent when the agora was placed next to burial grounds. For the Megarians, this was a conscious decision so that the dead could play an active role in communal affairs (Paus. 1.43.3). Other poleis only granted select individuals the right to be buried in the city center. The founder-leader (*oikistes*) was customarily buried and worshipped in the agora of new foundations, as in the case of Cyrene in North Africa (Malkin 2009: 374). The Athenians buried the remains of their local hero and model ephebe, Theseus, in their civic center; his adventures adorned a temple, the so-called Hephaisteion, that stood next to major civic buildings (Paus. 1.17.6).

The origin of the agora is much debated. Some scholars believe that the agora of the Early Iron Age was influenced by Minoan palace architecture (cf. Kenzler 1999: 323–6). Other scholars (e.g., Mazarakis Ainian 1997: 273) place more emphasis on the spatial configuration of Early Iron Age settlements and suggest that the open space in front of a ruler's house may have functioned as a "primitive agora." In any case, the earliest-known spatially defined agoras date to the eighth century BCE, a period that is characterized by the formation of cities and states. The earliest archaeologically attested agora was discovered in Megara Hyblaea in eastern Sicily, a settlement that was founded shortly after 750 BCE and covered a territory of about 600,000 m^2 (Mertens 2006: 64–72; cf. Hoepfner 2006: 3–4 for early settlements on Chios and Andros). The territory of the city of Megara Hyblaea was subdivided into five districts, each of which followed a slightly differently oriented

Agora in the Greek World, Fig. 1 Plan of the agora of Megara Hyblaea. (Courtesy: H. Tréziny)

grid system. The spatial planning reserved, among other spaces, an agora on the so-called Plateau Nord, an area of about 4200 m^2 that was located between two habitation districts, hence its unusual trapezoidal form (Fig. 1). This innovative urban planning solution was copied in Selinus, Miletus, and Piraeus, cities that were also laid out in converging grid-patterns. Another feature of urban planning, the main road connecting the agora with the main urban sanctuary, can be found in Megara Hyblaea's daughter colony, Selinus. At first, the agora of Megara Hyblaea consisted of an open, multifunctional space with altars, and it remains unclear whether its primary function was originally civic or sacred (Bergquist 1992: 134–5; de Polignac 1999). Monumental buildings, including temples, stoas, possibly a *bouleuterion* (council house), were constructed at the end of the seventh century BCE, while a heroon and a banquet house were added much later.

It is perhaps not surprising to find one of the earliest agoras in a colonial context, since "the phenomenon of colonization provided the overall rise of the polis with an enormous impetus" (Malkin 2009: 377). Although processes of urbanization were not uniform throughout the Mediterranean (van Dommelen 2005: 44), in most Greek settlements, they seem to have followed similar trends. Among other things, increasing importance was accorded to the community as a whole and to the public (*to koinon*, *to demion*) rather than the individual (*to idion*) or the household (*oikos*). If necessary, preexisting domestic structures and burials were cleared away for the creation of an agora. Designated spaces in the polis were assigned specific functions and later adorned

with purpose-built buildings. Once the civic center was established, it was seldom relocated, as can be seen in Argos (Pariente et al. 1998). This may also have been true for the agora of Corinth, which Donati (2010) recently posited beneath the Roman forum.

The evidence from the sixth and fifth centuries BCE is somewhat more plentiful, partly due to the construction of permanent administrative buildings and sanctuaries for polis deities. The agora of Metapontium in South Italy, for instance, not only housed a number of shrines and temples but also an impressive amphitheater-like installation that has been interpreted as an *ekklesiasterion* (building for popular assembly) with space for up to 8000 people. It is possible that the area was already used as an agora before 600 BCE, if the wooden remains discovered here can be interpreted as a stage (*ikria*) (Mertens 2006: 47). As in Selinus and possibly Syracuse (Mertens 2006: 76), it was an integral part of the planned settlement but it was not the focal point of its layout. The agora of Metapontium only became the heart of the city when the settlement expanded in the fourth century BCE. On the Greek mainland, the agoras tended to be less elaborate. The agora of Argos was adorned with two stoas and a temple for Apollo around the middle of the fifth century BCE.

The most famous agora is the agora of Athens, situated directly beneath the Acropolis in the district called the *Kerameikos*. It is also one of the best-published agoras (Camp 2010). This well-known agora is most likely the successor of an earlier agora. The location of the original agora and the date at which the later agora was monumentalized are much discussed. Papadopoulos (2003: 280–97; cf. Hoepfner 2006: 16, fig. 13) recently suggested that the earlier agora was located east of the Acropolis and relocated after 480 BCE. The chronology of the first major building phase in the western part of the new agora has been pushed back to the end of the sixth century BCE in recent scholarship; Papadopoulos (2003: 295) does not necessarily contradict this view, since he is mainly interested in determining when this place formally acquired its new function. By then, the principal public building of the Old Bouleuterion (Metroon) and perhaps the Royal Stoa had been erected in the northern part of the agora as well as altars and shrines, including the Altar of the Twelve Gods (Figs. 2 and 3). The Athenian agora also had its own fresh water supply; the public fountain house was part of a larger water management project that was celebrated on many black-figure vases. Some civic institutions such as the people's assembly were eventually established in the neighborhood of the agora, on the Pnyx or in the theater (McDonald 1943: 45, 47–51, 57–8). If many major buildings of the agora and the erection of boundary markers are associated with the Cleisthenic reforms in 508/7 BCE which resulted in "a united Attica" that was "a functional reality" (Anderson 2003: 5), it can be argued that this newly formed community, in turn, used the agora to strengthen its sense of community and collective identity. The Athenians measured the distances in Athens from the Altar of the Twelve Gods (Hdt. 2.7; *IG* II^2, 2640); the Panathenaic procession crossed the agora; monuments commemorating important people and milestones in the city's history, such as the end of tyranny and victories in the Graeco-Persian Wars, were erected in the agora. It is noteworthy that in addition to the meeting place in the city center, each Attic deme (small community of a citizen body that shared cults and festivals) had its own "agora" or "theatron," as they were called in inscriptions, in the fifth and fourth centuries BCE (Kolb 1981: 62–74).

Herodotus (5.101) is one of the first authors to refer to the agora as a marketplace but it soon became the quintessential function of this public place. Some Greek authors such as Herodotus (2.39) and Xenophon (*An*. 1.5.6) even used the term to denote market places in non-Greek societies. Specific products such as vegetables, meat, books, and perfumes were sold in designated spaces in the agora of Athens (e.g., Ar. *Lys*. 557-8), and these spaces were in turn named by the Attic orators after the goods sold there (Poll. 9.47; 10.19). Stoas often had rooms used as shops and workshops that were rented out by the polis authorities. The Attalos stoa on the east side of the agora of Athens consisted of 42 rooms (approximately 5 m by 5 m) on two floors.

Agora in the Greek World, Fig. 2 Plan of the agora of Athens, c. 500 BCE. (Courtesy: Agora Excavations)

This additional function made the agora the perfect social meeting place, hence the term *agoraios* for someone who spends much time there (e.g., Hdt. 1.93). For Socrates, the agora was the ideal place to engage passers-by in philosophical discussions. Aristotle (*Pol*. 1331a-b) argued for a separate commercial agora. Two agoras were the norm for most Hellenistic cities. While the market place can be found near the harbor in Ephesus and Miletus, the civic and the commercial centers were placed next to each other in Kamarina and Morgantina. The two agoras of Priene were close to each other but of different sizes.

The agora was still a characteristic feature of Greek cities in the late Classical and Hellenistic periods even though their autonomy was often limited to self-government and depended on the approval of imperial powers, and while new institutions emerged and became characteristic features of Hellenistic cities. This was also true for later writers, including Dio Chrysostomus (*Or*. 48.9) and Pausanias (10.4.1). By the Hellenistic period, the agora was monumentally defined and quite often closed off from the surrounding area by monumental public buildings. Yet it was not standardized. One of the most characteristic

Agora in the Greek World, Fig. 3 Model of the agora of Athens, c. 500 BCE. (Courtesy: Agora Excavations)

building types of this period was the stoa defining the boundaries of a central area and housing commercial establishments, as on Delos, at Magnesia on the Maeander and Miletus. Two adjacent sides of the agorai of Kassope, Kolophon, Orchomenos in Arcadia, and Syracuse were closed off by porticos, while the agora of Morgantina in Sicily and that of Thelpousa in Arcadia were framed on three sides. The agora at Messene is a typical example of a completely closed agora. Other cities placed theaters on the edges of their agoras. In the cases of Akrai, Assos, Elis, Mantineia, Morgantina, and Metapontium, the theater served as an *ekklesiasterion* (Kolb 1981: 88), while the theater of Kassope has been interpreted as a *bouleuterion* (Hoepfner 2006: 23). In addition, wealthy benefactors (*euergetai*) sponsored individual buildings within the agora or completely new building complexes. Famous examples of the former include the Stoa of Attalos at Athens and the colonnades and exedrae of the so-called Agora des Italiens on Delos, the function of which is still debated. The most famous example of the latter is perhaps the Upper Agora of Pergamon on the edge of the acropolis (Figs. 4 and 5), which was part of the major building project of the Hellenistic King Eumenes II (197-160/59 BCE). As the administrative and religious center of the newly organized royal metropolis of the Attalids, it was adorned – like most Hellenistic agoras – with statues, dedications, and altars (Radt 2001: 48).

The Upper Agora of Pergamon moreover exemplifies characteristically Ionian features according to Pausanias' typology of agoras, namely, the colonnades that enclose large sections of the agora (but do not obstruct the view to the monumental altar; Fig. 5). Many newly founded, refounded, and even modernized late Classical and Hellenistic cities in Ionia used the so-called Hippodamian town plan, in which streets are laid out on a rectangular grid around central, often colonnaded public spaces. Another famous example is the agora of Priene, a city that was refounded in the fourth century BCE. When Pausanias, in the second century CE, visited the agora of Elis, he noted that the local agora with "porticoes separated from each other and with streets through them" was rather old-fashioned and stood in sharp contrast to the agoras of the cities of Ionia and of the Greek cities near Ionia (6.24.2; Jones 1933). The closed-off Ionian agora with few formal entrances may be seen as the predecessor of the forum, the open square, or market place of a Roman settlement or town, even if some of its characteristic features such as the podium temple and basilica were developed in Italy, and some aspects of its layout such as the new architectural concept of a grandiose approach to the forum, as

Agora in the Greek World, Fig. 4 Plan of the agora of Pergamon, second century BCE. (Courtesy: K. Rheidt)

Agora in the Greek World, Fig. 5 Reconstruction of the Upper Agora of Eumenes II. The reconstruction of the north niche in the foreground is hypothetical. (Courtesy: K. Rheidt)

found at Ephesus, Pergamon, and Hierapolis, were introduced much later.

Key Issues/Current Debates

The archaeological evidence for the emergence of the agora is scarce. The location and appearance of the early agora is best documented in systematically planned poleis in southern Italy and Sicily. Here, agoras are centrally located, open places that serve the needs of the community. The earliest civic centers of cities which were never planned as a whole, such as Corinth and Athens, are often difficult to locate or can only be traced archaeologically when buildings were placed along their boundaries. Literary references to an earlier agora exist occasionally, as in the case of Athens, but no traces of this old agora that is mentioned in a note of the second century BCE writer Apollodoros (FGrH 244F 113 and preserved by Harpokration) have been discovered. Owing to the poor archaeological documentation of early poleis, the frequent references to the agora as a social institution and as a place of communication in the epics of Homer have received much scholarly attention. However, the Homeric poems cannot be used as a historical source even if the date at which they were written down can be determined. While it is generally accepted that the Homeric world cannot be mapped onto Bronze Age or Iron Age Greece, it is still debated how to best explain inconsistencies within the poems and how to conceptualize the sociopolitical configuration of Homeric society.

Future Directions

The main area for future research is the early agora. The exact relationship between the origin of the agora and the birth of the polis and urbanization processes needs to be explored in more detail. New discoveries will play a major role in this discussion, since many of the excavated sites have long occupation histories that make it difficult to detect open space with little to no architectural features. A further research area concerns the development of the agora in the Black Sea region.

Agrarian Landscapes of the Historic Period

Tom Williamson
School of History, University of East Anglia, Norwich, UK

Introduction

Agrarian landscapes of the historic period have an often fragile archaeology. Most are still used to produce food, and the fences, walls, and hedges which form their principal remains, or the earthwork traces of earlier systems of farming and land division which survive within them, are thus vulnerable to destruction. Those living and working within what appear to be everyday, functional landscapes are often unaware of their antiquity or historical significance.

Definition and Historical Background

Across much of medieval Europe peasant communities exploited most uncultivated land in common. Grazed intensively for centuries, and cut for fodder, fuel, and much else, these areas developed as particular forms of habitat – with their own individual suites of flora and fauna – such as moorland, fens, or heaths. In addition, in many districts the arable land was farmed in "open fields," in which the properties of cultivators lay intermingled in the form of narrow, unenclosed strips (each usually less than 10 m wide and frequently less than 7 m), across which various communal routines were imposed. Usually, for example, the same crop was cultivated by all those holding land in a particular section of the fields, and large and often continuous sections of the arable lay "fallow," or uncropped, every second or third year, so that they could be dunged by livestock and recover fertility. Open-field strips were usually slightly sinuous in plan, having been distorted over the years. Many took the form of a shallow "reversed S," caused by the

way that the plowman moved to the left as he approached the end of the strip, in order to avoid too tight a turning circle.

Open fields took many forms. In Sweden, parts of Denmark, central England, northeastern France, southern Belgium, and central-southern Germany, extensive and highly communal systems existed. These were farmed from large villages and contained the intermixed holdings of substantial numbers of landholders. But more "irregular" field systems, containing the holdings of fewer farmers and normally associated with dispersed settlement patterns, could be found widely across northern Europe, from Cornwall and Brittany in the west to Hungary in the east. Other variants existed in some Mediterranean countries, including Italy and Spain. Open fields first developed in the early medieval period, in many districts before the tenth century, and possibly as early as the seventh. There has been much debate about their origins. The intermixed properties seem initially to have developed as a consequence of partible inheritance and piecemeal colonization (as new land was divided in an equitable fashion among those who had worked to reclaim it). But the emergence of more complex and corporate forms was probably the result of population pressure, technological change (especially the shared use of a large moldboard plow), and the need for elites to facilitate the extraction of rents and services. Their creation involved a measure of systematic planning and, in some cases, the reorganization of existing patterns of settlement.

Open fields disappeared from most of northern Europe between the fifteenth and the nineteenth centuries, but have left a number of archaeological traces. In some areas unhedged and intermixed parcels, larger than the original strips and no longer subject to communal regulation, still survive, as in parts of the Netherlands and France. Elsewhere their essential layout is preserved, in more simplified form, in the current pattern of walls and hedges. This is because in many districts open fields disappeared through "piecemeal" enclosure: that is, landowners gradually consolidated scattered holdings through purchase and exchange, surrounding groups of strips with walls or hedges which thus perpetuated the sinuous, parallel patterns of the former landscape. In addition, in areas of heavy soil individual strips were often plowed in ridges, to facilitate drainage. Because enclosure was often associated with a shift from arable farming to specialized livestock production or dairying, these can be preserved in grass fields as the earthworks known as "ridge and furrow" (Fig. 1), found in particular in parts of the English Midlands but also sporadically in northern France and Germany.

Key Issues

Not all areas of Europe were dominated by open-field agriculture. In the *bocage* of western and much of central France, for example, and in the "woodland" districts in both south eastern and western England, landscapes of enclosed and often irregularly shaped fields, or ones in which enclosed fields and small patches of open fields coexisted, could be found. Both the relative extents of open fields, and their particular character, were the consequence of the complex interplay of demographic, economic, environmental, and social factors, although archaeologists and historians continue to debate the relative importance that should be attributed to each.

The agriculture of much of northern and western Europe was transformed in the postmedieval period, with the development of greater regional specialization and major increases in productivity. These developments were the consequence of wider changes and pressures which included rapid population growth (especially from the eighteenth century), the emergence of developed market economies, and industrialization. Agricultural "improvement," to use the fashionable eighteenth-century English term, occurred at differing rates in different areas, depending on the wider character of social and economic relations. By the eighteenth century the agricultural primacy of England and the Netherlands was widely accepted, and the new practices which had been developed there widely emulated. New fodder crops – turnips and other "roots," and grasses like clover – were introduced into field rotations, reducing the need for land to lie fallow, and agropastoral areas and other commons and forests were brought into more intensive cultivation. These changes involved the end of communal forms of exploitation and a shift to more individualistic modes of farming. Many areas of common land were now allocated in hedged or walled parcels to particular owners; properties in open fields were either subject to gradual piecemeal consolidation or were reallocated in a planned fashion as private fields – in England, for example, by parliamentary enclosure and in Denmark through the process of *ensgifte*. Nevertheless, these developments were not universal, and open fields were still being reorganized, in Germany and the Netherlands, as late as the eighteenth century. In parts of central and eastern Europe, they survived into the twentieth century and in some cases up until the present.

The enclosure and "improvement" of marginal land in postmedieval Europe had major effects on biodiversity. This period saw, for example, the destruction of more than three quarters of the heaths in Denmark and even more in Brittany. In part, reclamation of such land was made possible by the substitution of organic materials for coal and iron, as Europe industrialized, for heaths, moors, and other rough ground had originally been cropped for fuel and fodder, just as many wetlands had been regularly dug for peat. Indeed, it was the drainage of wetlands which was one of the most striking features of the postmedieval period. Much coastal marsh had been reclaimed in medieval times, but the period from the sixteenth century saw an increase in drainage activity and its extension to the more problematic wetlands, especially those formed in peat rather than marine clays. The Netherlands had long experience of land drainage, carried out from the fifteenth century with the assistance of windmills, and it was largely Dutch engineers who directed postmedieval reclamation in the Fenlands of eastern England, in the Marais de Poitou and other French marshes, in Lammefjorden and elsewhere in coastal Denmark, and in Poland and north Germany.

Planned enclosures of commons and open fields were assisted by the development of more sophisticated systems of surveying and land measurement, and fields created from the seventeenth century were frequently straight-sided and geometrically shaped: land freed from communal control was now, more than ever, a commodity to be measured and exchanged. Such landscapes can be found across much of northern Europe, although they have survived modern agricultural developments best in the English Midlands, parts of the Netherlands, and southern Scandinavia. Some schemes of enclosure took particularly abstract geometric forms, such as the grid of roads and drainage ditches created when the

wetlands at Beemster in the Netherlands were drained in the seventeenth century – now a World Heritage site. Indeed, the new agrarian landscapes of the post-medieval centuries were not purely practical and agricultural in character. They represented the rational transformation of nature and the triumph of modernity over tradition, and it is noteworthy that in this period, in contrast to the Middle Ages, elites often consciously identified themselves with agricultural activities. This was especially true in England, where major eighteenth- and nineteenth-century landowners like Thomas Coke of Holkham in Norfolk were prominent "improvers," the landscapes of their estates often combining, in complex ways, aesthetic and agricultural elements. Many created "model farms" with buildings which were both practical and ornamental in character, often laid out in some whimsical "Gothic" form. Major landowners in other European countries did the same: notable examples include the Gothic farm complex created at Racconigi in Piedmont by Charles Albert, Prince of Carignano, in the early nineteenth century (Fig. 2).

Enclosed fields thus proliferated in the post-medieval period in Europe, and the ways in which they were bounded exhibited elements of both continuity and change with medieval practice. Boundaries in drained wetlands took, in all periods, the form of water-filled ditches. These served to drain the land but also – in areas where livestock farming was important – functioned as "watery fences" to restrain sheep or cattle and to provide them with drinking water (Fig. 3). Reclaimed wetlands are thus characterized by an absence of hedges, fences, or walls. In upland areas dry stone walls were generally employed to enclose land, and in the course of the post-medieval period, these often took increasingly regular forms. In lowland districts hedges were generally used (Fig. 4). In medieval and early postmedieval times these had normally been planted with a range of species, partly because of the difficulties of accessing large quantities of hedging material but also because – as well as functioning as stock-proof barriers – they also served as a source of fuel wood. By the eighteenth century the fashion for planting single-species thorn hedges was becoming established, especially in England, as the increasing availability of coal lessened the importance of hedges as a fuel source. Such hedges served to express the divorce of large, modern landowners from the archaic practices of a peasant economy.

International Perspectives

The range of agricultural landscapes found elsewhere in the world, and which were encountered by Europeans during the great postmedieval diaspora, are too varied to be considered in detail here, but were again shaped both by practical agrarian considerations and by wider social, economic, and ideological contexts. In archaeological terms, the most striking features include the great systems of terraces which are found across much of the Far and Near East, and in the Americas, from the southwest of the United States as far south as northern Argentina. Terraces fulfilled a range of functions. They provided a level area of cultivatable ground in mountainous regions, helped control soil erosion, and assisted in water management. The latter concern looms large in agricultural systems on a global scale, from an early date: examples include the complex forms of perennial irrigation practiced in various parts of the Middle East and Mesoamerica, with water conducted to crops through complex systems of channels, and the systems of basin irrigation practiced in Egypt, where seasonal floods are constrained within embanked fields.

Archaeological remains of irrigation are often, in semiarid areas, one part of more complex agrarian strategies. Across much of central and southern America, and in some parts of the USA, "raised fields" – elevated planting areas separated by canals or ditches, often covering very extensive areas of ground – served both to provide drainage and irrigation, depending on the season. The canals also provided a microclimate, giving some protection from frosts, and served as a source of fertility, for their nutrient-rich mud was dredged and spread on the fields.

When European colonists encountered indigenous peoples, existing agricultural landscapes often continued with little change, especially in contexts of colonial dominance rather than large-scale immigration. The great rice terraces of the Ifugao in the Philippine Cordilleras have thus been continuously used and maintained through more than 2000 years. Where agrarian landscapes possessed relatively few structural elements or the economy was largely organized around hunting and gathering, in contrast, and where the immigrants were themselves numerous, they were more likely to impose elements of their own ways of organizing a countryside – although sometimes these were inappropriate and short-lived, like the attempts by early settlers in New England to lay out fields modeled on the open fields of their homelands. In the southern coastal states of North America, in particular, elements of the landscape of English eighteenth-century estates were often replicated, although here organized mainly around slave production rather than tenanted farms. The long European experience of reclaiming wetlands was also employed in the New World, to create drained marshes like those of the French Acadian settlement at Grande Pré in Nova Scotia, currently a candidate for World Heritage status. But much about the agrarian landscapes of North America was new. In the original thirteen states, field boundaries were normally fenced, or in parts of New England walled, rather than hedged, largely due to the local abundance of wood. Initially post-and-rail fences were created but in the southern states these were soon replaced by the split rail zigzag fences still characteristic of the area. As the colonists spread west, into the northwestern territories, highly rectangular field patterns were created through the organized subdivision of the great abstract grid imposed on the landscape under Thomas Jefferson's direction as an expression of the rational and egalitarian principals of the young republic. This was further extended into the territories purchased from the French in 1803. Here, in a landscape singularly lacking in wood and timber, the fields created as the grid was subdivided were bounded by various forms of wire fence, and especially by barbed wire (invented in the USA in the 1860s), rather than by fences of wood. Across the interior of Australia, too, parcels of land bounded by wire fences, currently the subject of archaeological research and classification, proliferated in the course of the nineteenth century, rendering redundant the practice of running mobile sheep flocks under the control of shepherds.

Viewed in global terms, agrarian landscapes display an almost limitless variety, born not only of agricultural and economic factors but also of wider social, economic, and ideological influences.

Agrarian Landscapes: Environmental Archaeological Studies

Nicholas Branch
Department of Archaeology, University of Reading, Reading, UK

Introduction and Definition

Environmental archaeology has grown to be a major subdiscipline of archaeology, which utilizes scientific approaches from many different backgrounds of academia, including geography, geology, biology, physics, and chemistry (Butzer 1982; Dincauze 2000; Bell and Walker 2004; O'Connor and Evans 2005). We can therefore define environmental archaeology in archaeology as "*the study of the environment and its relationship with people through time*"; this has in turn led with landscape and stratigraphic formation and modification processes and draws mainly on geological, sedimentological, and soil science analytical techniques. Both zooarchaeology and archaeobotany focus not only on human economies and subsistence (diet, health, and nutrition) of both wild and domesticated animals and plants (*paleoeconomy*) but also on broader environmental reconstruction (*paleoenvironment*), such as vegetation succession (Branch et al. 2005).

The reconstruction of agrarian practices, and their landscape and environmental context, is reliant therefore upon the application of scientific procedures utilized in *geoarchaeology*, *zooarchaeology*, *and archaeobotany.* Geoarchaeological procedures include sediment/soil classification, micromorphology, particle size analysis, magnetic susceptibility, and multielement geochemistry. The relevant archives investigated include not only archaeological features, such as ditches and pits, and ancient soils (paleosols), but also geological archives, such as floodplains (alluvium), slope wash in dry valleys (colluvium), aeolian deposits, volcanic and cave sediments, and organic and mineral sediments in bogs and lakes. In bioarchaeology (both *zooarchaeology and archaeobotany*), the key proxies (subfossils) that are recovered from these archaeological and geological archives include animal bones, terrestrial Mollusca, charred seeds and other plant parts, charcoal and phytoliths, and also pollen, fungal spores, and waterlogged seeds. Precise identification and recording of these proxies, and where applicable the utilization of data from ethnographical, ethnohistorical, and documentary sources, is key to the reconstruction of agrarian practices. Good preservation of charred plant remains on many West Asian and North African archaeological sites, for example, combined with well-established ethnographic models detailing traditional agricultural practices, has indicated the status of the arable fields (e.g., soil type, moisture content), the system of cultivation (e.g., intensive, extensive), manuring regimes, tillage practices, and sowing, harvesting (e.g., uprooting, plucking, or cutting with a sickle or scythe), and processing methods, especially for free-threshing cereals (durum wheat and naked barley), hulled barley, and glume wheat (emmer, spelt, and einkorn). Studies make frequent use therefore of both qualitative and quantitative approaches to evaluate the potential of proxies to provide robust reconstructions of agrarian practices and their wider environmental context. These approaches include the creation of taphonomic models to differentiate between "local" and "regional" signatures of human activity (e.g., pollen analysis) and to elucidate the role of diagenesis in the creation of the subfossil assemblages (e.g., animal bones, pollen). The application of "modern analogue" studies is especially important here, and this has been ably demonstrated with respect to West and Southeast Asian investigations of the history of wheat/barley and rice cultivation (respectively), which has involved gathering essential information on the environmental variables

for their growth within specific agricultural regimes (e.g., dry-farmed, irrigated fields, crop rotation).

The integrated study of these archives, both archaeological and geological, and their proxies permits environmental archaeologists to address a range of research themes that may be specific to a single site (e.g., Neolithic settlement), and an event of short duration (e.g., woodland clearance), or relevant at a regional to global scale, and spanning several millennia. Whatever the spatial and temporal scale, collectively they provide important information on the origins and spread of agricultural practices, the development of agricultural systems through time, the impact of agriculture on the landscape and environment, and the changing nature of human diet, health, and nutrition.

Key Issues/Current Debates

Environmental archaeological studies make a considerable, ongoing contribution therefore to improving understanding of the origins and spread of agriculture and the accompanying landscape and environmental changes. Western Asia (from present day Iran in the east to Turkey in the west), for example, is acknowledged as one of the geographical centers for plant and animal domestication ~12–10,000 years ago. In this area, many of the food staples that remain important today, such as wheat, barley, rye, lentils, peas, sheep, and cattle, were morphologically and genetically altered through the processes of domestication and then subsequently spread across Europe over ~6,000 years (Zeder 2008). In the Jordan Valley, an important region of intensive environmental archaeological research, investigations provide a complex picture of farming and its environmental context (Mithen and Black 2011). Charred plant remains and animal bone assemblages indicate mixed farming, with the cultivation of a broad range of key plant domesticates from the start of the Neolithic (~12–6,500 years ago) that included emmer and einkorn wheat, barley, as well as lentil, pea, chickpea, bitter vetch, and flax. The evidence suggests that significant landscape modification accompanied the transition to farming, with programs of water management to feed agricultural land enclosed within terrace walls, thereby enhancing the probability of a regular crop yield. According to the pollen data, the onset of the Chalcolithic (~6,500 years ago) was marked by the first clear signs of woodland clearance for farming, which became extensive ~2,000 years ago with significant deforestation associated with metallurgical activities. These studies have also suggested that periods of rapid climate change in the East Mediterranean significantly influenced the direction of agricultural activities, with periods of higher precipitation seemly favoring the intensification of cultivation at ~6.5–4,000 and ~2.5–1,300 years ago, with olive, grape, and walnut production at its maximum during the Roman-Byzantine period.

Similarly, in SW Turkey, extensive pollen-based land-use histories have revealed evidence for widespread Bronze Age clearance and farming ~3,200 years ago (Eastwood et al. 1998). These studies indicate that, depending upon elevation and local factors, olive, walnut, chestnut, pistachio, and vine were cultivated, alongside cereals, and managed in the woodland. In E Turkey, lake sediment records indicate pronounced human activities from ~3,800 years ago, which became more intensified in the last ~600 years, with evidence for walnut cultivation and the expansion of pastureland, while in central Turkey, there is outstanding evidence for the imprint of agrarian activities on the landscape from the late Roman period based on pollen analysis (England et al. 2008). The presence of walnut, olive, vine and chestnut, and rye, wheat, and barley cultivation suggests arboriculture, pastoralism, and cereal cultivation. At 670–950 CE, there was a marked decline in agrarian practices during the "Dark Age," which was succeeded at 950 CE by renewed cereal cultivation and pastoralism. The impact of Neolithic agricultural practices on the landscape in this region remains less well understood, however, despite the good archaeological evidence for settlement and farming. Indeed, the pollen evidence indicates a predominantly wooded landscape with seemingly low levels of human interference. An alternative interesting possibility is that this wooded landscape was

"managed" by deliberate burning to create suitable grazing land and to enhance conditions for cultivation (Roberts 2002; Wick et al. 2003).

In Southeast Asia, environmental archaeological studies of agrarian practices, and their landscape and environmental context, have arguably been less intensively investigated than in West Asia. Comprehensive studies in the Lower Yangtze region (China), however, have permitted an improved understanding of prehistoric farming and one of the key crops for this region: rice. Studies have shown that rice cultivation commenced here ~6.9–6,600 years ago and certainly as early as ~8,000 years ago in other parts of China. This systematic study using rice grains, phytoliths, and spikelet bases has also provided important evidence for the composition of weed species typically associated with rice cultivation, thereby providing a further important evidential base from which to infer cultivation (Fuller et al. 2009). The landscape context for the cultivation involved both water management and burning.

In Europe, environmental archaeological studies have revealed that the spread of agriculture had far-reaching consequences for the landscape and environment (Kaplan et al. 2009). The evidence from both archaeological and geological archives suggests that although the early stages were a mixture of permanent settlement and residential mobility, both cultivation and animal husbandry of the main domesticates from West Asia required the clearance of woodland, which was often associated with biomass burning ("slash and burn"). Although many records suggest that clearance was temporary ("shifting cultivation"), which permitted the woodland to recover, during prehistory, the evidence indicates progressive deforestation of mature coniferous (e.g., fir) and/or deciduous (e.g., elm, lime, oak) woodland and the introduction of field systems and, in some areas, agricultural terracing. This led to the creation of "plagioclimax communities" that were sustained by human interference, e.g., grasslands, heathlands, and moorlands of Northwest Europe and the scrubland of Mediterranean Europe (although regional climatic and edaphic factors were also important in their formation and maintenance).

Evidence for deforestation due to agricultural practices, namely, cereal cultivation and/or animal husbandry, from the Neolithic period onwards is widespread in upland and lowland parts of Europe. Indeed this key "anthropogenic signature" in subfossil records from lake sediments and bogs, combined with archaeological evidence for mixed farming (e.g., charred plant remains and animal bone), has enabled the development of complex regional models of human-environment interaction. For example, pollen data from Northwest Europe indicate two pronounced events, which have been strongly associated with human activities: Neolithic "elm woodland decline" (Parker et al. 2002) and Bronze Age "lime woodland decline" (Grant et al. 2011). These two trees formed important components of the natural forest cover. Debate over the cause, or causes, of the "primary" decline in elm woodland has continued for several decades, with evidence from Britain and Ireland indicating a very rapid decline in ~36 years (6,343–6,307 years ago). For this reason, woodland clearance for cultivation and grazing, as well as the harvesting of elm leaves, twigs, and branches for winter fodder and bedding, may be a secondary cause. Instead, the rapid spread of disease (caused by ascomycete fungus *Ophiostoma ulmi*), in conjunction with both human activities and climate change (increased continentality), may collectively have contributed to the decline. Whatever the precise cause, pollen analysis has shown that the decline of elm woodland is often associated with cereal cultivation and possibly animal husbandry (presence of dung beetles), which suggests that human groups, albeit at dispersed, low population levels during the Neolithic, were having some localized impact on elm woodland. This probably formed part of a system of forest farming involving residential mobility, short-term woodland clearance, burning, woodland management (pollarding/coppicing), and cultivation. In Ireland, the discovery of the Neolithic "céide fields" provides an exceptional example of a coordinated approach to landscape modification following the introduction of agriculture that provides unequivocal evidence for a marked

reduction in woodland cover (pine, oak, elm, hazel, and birch) and the establishment of grassland and finally heathland.

The lime woodland decline, which commenced in Britain ~5–3,000 years ago (Late Neolithic to Late Bronze Age), has also been strongly linked to clearance of the landscape for farming, as well as the provision of fodder for animals. Although, like elm, alternative explanations have been proposed, the overwhelming evidence for its association with contemporaneous cereal cultivation and settlement activities, together with the diachronous nature of the decline ("different times in different places"), provides strong support for a human cause. For example, in S England, the environmental archaeological evidence suggests widespread use of landscape units (valley bottom and side, and hilltop) with mixed farming of emmer wheat and six-row barley, as well as einkorn, bread, and spelt wheat, and pastoralism involving cattle, sheep, pig, and goat that were probably moved on a seasonal basis ("transhumance"). These practices caused not only a change in natural vegetation cover from the Bronze Age onwards (e.g., widespread heathland formation) but also soil status (e.g., podzol and rendzina formation), including a reduction in nutrient quality and pH (acidification), accelerated erosion (colluviation), and paludification (wetland or bog formation) due to impeded drainage. During later prehistory, and into the historic periods, environmental archaeological evidence for the wider landscape and environmental context of farming practices in NW Europe, especially Britain and Ireland, is less available due to the paucity of intensive studies and availability of suitable sites. Nevertheless, those studies conducted in Britain and Ireland suggest marked intra-regional differentiation in the agricultural landscape, with significant temporal variations in land use, e.g., afforestation, pastoralism, and cereal cultivation (Fyfe et al. 2004). Those studies that have benefitted from the combined use of geological, archaeological, and historical archives have provided valuable information on medieval and later agrarian landscapes. In Ireland, for example, studies have revealed that although cattle farming, and barley and oat cultivation, formed the basis of the medieval economy, a shift towards cereal cultivation occurred from 770 CE as a possible response to wetter climatic conditions, which worsened during the Little Ice Age (1350–1850 CE), and led to major changes in settlement patterns and agrarian practices. Indeed, the role of climate change in determining the direction of agrarian activities in Britain and Ireland, and throughout the world, has been a considerable point of debate. For example, pollen-based studies of later Bronze Age farming in Scotland indicate that ~2,900 years ago, a widespread period of climatic deterioration commenced across NW Europe and resulted in a change in land use, rather than abandonment, with the increased importance of grazing in upland areas, and the expansion of settlement and agricultural land in the lowlands (Tipping et al. 2008). In this example, the evidence indicates that adaptation, rather than collapse of the agricultural system, caused a change in farming activities, which implies a high degree of resilience to environmental stress caused by climate change by human populations living in "marginal" agricultural areas.

In the Mediterranean region, environmental archaeological studies of landscapes have debated the influences of human activities, especially farming, and climate change for many decades. Although the debate continues, there is now a substantial body of sedimentary evidence linked to the archaeological record for catastrophic erosion due to woodland clearance and land use, especially from the Bronze Age onwards (e.g., Greece) (Klinge and Fall 2010). The subsequent construction of agricultural terraces throughout the Mediterranean may therefore have been an important conservation measure to mitigate the risk of further erosion and to ensure the sustainable supply of food for an expanding population. Indeed, environmental archaeological data suggest that abandonment and/or neglect of the terraces caused renewed erosion, accelerated by unmanaged vegetation growth and grazing animals. Periods of erosion have been associated therefore with phases of expansion and contraction in agricultural activities. The modification of the morphology of the landscape, changes in

natural soil quality, and reduced susceptibility to erosion, through the Bronze Age development of terrace agriculture in the Mediterranean, was therefore a major innovation (~3,800 years ago). This provided a means of creating a more sustainable agricultural system and ultimately provided an ideal situation for the widespread management of important cultivars, such as olive.

In addition to terracing, an important aspect of Mediterranean agriculture has been transhumance involving the movement of livestock on a seasonal basis between lowland and upland areas, sometimes over considerable distances (Barker 1985). These practices were probably in place from the Early Neolithic, but the expansion of farming into mountainous regions of the Mediterranean from at least the Late Neolithic led to further development of the transhumance network. In Greece, for example, evidence for sheep/goat, cattle, and pigs provides a valuable insight into early agrarian practices, which included the cultivation of emmer and einkorn wheat, and two-row barley and lentil. These crops were initially cultivated in a forested landscape in localized clearings, but pollen records reveal a progressive reduction in woodland that coincided with the development of a broader subsistence economy. In Italy, a similar dependence on emmer, barley, and legumes, as well as sheep and goats, recorded in lowland open air and cave settlements, seemingly led to limited landscape modification until the Late Neolithic (~6,100 years ago). At this time, pollen records from mountainous areas indicate a gradual reduction in woodland cover (e.g., elm and lime) or the changing dominance of tree taxa (e.g., fir to beech), suggesting the increasing influence of human activities. The history of beech woodland in N Italy, in particular, has received considerable attention because of its ability to invade adventitiously mature woodland due to one or more causes, including disturbance and climate change to favorable conditions. The remarkable correlation at many sites between the expansion of beech woodland, increased biomass burning, evidence for pastoralism (archaeological and pollen stratigraphical), accelerated erosion, and the decline of other tree taxa strongly suggests that agrarian practices may have initiated changes in the conditions necessary for beech growth leading to its dominance in vegetation communities (Branch 2012).

Outside Asia and Europe, environmental archaeological studies have demonstrated the existence of multiple centers of plant and animal domestication around the world, with the timing of the transition to farming varying considerably. To highlight this global phenomenon, the broad timing of plant domestication in key centers is illustrated (all "years before present day"): Australasia (e.g., yam and banana) ~7,000; N Africa (e.g., millet and sorghum) ~4–3,000; N America (e.g., squash and sunflower) ~5,000; Mesoamerica (e.g., squash and maize) ~10–8,000; and S America (e.g., squash, arrowroot, yam, cotton, sweet potato, beans, peanut, manioc, chilli pepper, potato, and quinoa) ~10–5,000. Although the precise reason or reasons for the initiation and adoption of plant cultivation and animal husbandry in many parts of the world remain unclear, the key factors were undoubtedly geographically variable and included measures to mitigate the risk of failure of annual food supplies, population pressure, and climate change (Stahl 1994).

In S America, evidence for landscape modification based on pollen and phytolith data suggests that cultivation probably commenced at least ~7,000 years ago in northern countries, such as Panama, and involved maize, arrowroot, and economically important trees. Throughout S America, the development of raised field agriculture transformed the landscape and enabled the development of a sustainable system by creating a distinctive microclimate and by improving the soil status and nutrient cycling. Similarly, terracing throughout S America is extensive with an estimated ~1,000,000 ha in Peru alone. The importance of terrace agriculture in many parts of the Andes, like the Mediterranean region, cannot be overstated. Environmental archaeological studies indicate that the construction of terraces transformed the morphology of the landscape while also creating the basis for a highly innovative and sustainable agricultural system that primarily permitted the cultivation of maize and

quinoa, an interpretation verified by parallel studies of archaeological and geological archives using pollen and phytolith analyses. Archaeological studies have permitted detailed investigations of the terrace structural organization and development, especially their irrigation and drainage, and the physical properties and composition of the soil infilling the terraces using techniques such as micromorphology and geochemistry. Studies in central and southern Peru, for example, have revealed multiple phases of terrace construction during later prehistory, with evidence for possible soil enrichment through manuring and/or fallow periods, and localized landscape erosion triggered by the construction activities (Branch et al. 2007). Interestingly, there is evidence in several parts of Peru for the abandonment of terraces, such as those of the Wari civilization (500–1000 CE), and their subsequent reconstruction prior to the Colonial Period (1533 CE). While the persistence of terrace agriculture confirms the importance of terraces in the agricultural system, the precise reason for their occasional abandonment remains unclear. Correlation of archaeological and paleoecological studies with paleoclimatic records from ice cores in Peru and Bolivia indicates, however, that periods of rapid climate change, e.g., at ~1000 CE, may have been the cause. The onset of drought therefore may have led to the collapse of Wari irrigated terrace agriculture, an argument supported by the contemporaneous decline of the "Tiwanaku civilization" raised field agriculture on the shores of Lake Titicaca. The development of terrace agriculture and maize cultivation in the intermontane valleys of the Andes has been linked to the formation of complex social and economic systems, e.g., Wari. Maize growth formed part of a broadly defined agricultural model that saw the utilization of a wide range of ecosystems, and included the cultivation of bitter potatoes, and herding of llama and alpaca, above the maximum elevation of maize cultivation (3,700 m above sea level).

In Mesoamerica and N America, the history of maize has also been the primary focus of many environmental archaeological studies. The main sources of evidence have been phytoliths in pottery residues and dental calculus, as well as in soils, lakes and bogs, and macrofossil specimens, and associated archaeological artifacts indicating food production. Evidence has pointed to the conversion of the landscape and environment by shifting cultivation ("swidden"), terrace agriculture, and raised field systems. The collapse of these intensive practices due to nutrient depletion and soil erosion has been strongly associated with the demise of the Mayan civilization (Santley et al. 1986). Alternatively, the evidence for a well-developed system of environmental and crop management suggests that other external factors may have triggered the collapse. The evidence for extensive deforestation and hydrological changes, together with an over-reliance on maize cultivation, suggests, however, that the Maya did not facilitate the development of a long-term sustainable agricultural system.

State of Knowledge and Current Debates

For few years, pre-Columbian agriculture in Amazonia begins to be better understood, thanks to more accurate studies, exempt of the classical, and too simple dichotomy between the poor interfluvial lands and the fertile floodplains. William Denevan (2001) published a useful synthesis on indigenous agriculture in South America outlining that farming patterns observed today are likely to be very different from those that existed before the European Conquest and the introduction of iron tools. In fact, many pre-Columbian agricultural techniques do not exist anymore today in the region. For that reason, ethnographical analogy is not very useful to understand them. Other data must be taken into consideration.

Pre-Columbian Amerindians transformed deeply the Amazon, whether the vegetal cover, the topsoil, the nature of the sediments, and even the modeling of soil. These changes, volunteers or not, were observed in the first place by geographers, anthropologists, or archaeologists some 30 years ago (Posey 1985). Rainforest covering the region is then less natural and less exuberant as thought. During millennia, the former inhabitants

weeded, planted, multiplied, crossed, associated, or improved species. For instance, William Balée (1987) estimated that about 12% of the Amazon basin was manipulated in its vegetation by the indigenous. A close observation of the Amazon vegetation leaves no doubt about the importance that had the ancient human intervention in its current state (Clement et al. 2015). Recently, it had been shown the long term and strong influence of pre-Columbian societies on Amazonian vegetation by revealing the relative abundance and richness of domesticated species near archaeological sites (Levis et al. 2017).

In a comparable way, scholars brought to light soils partially created by man. The *terras pretas* or "Amazonian dark earth" (ADE) are compounds, dark and fertile soils associated with remains of implementations and naturally enriched with debris of occupation, coal, and ash. Many have wondered if they are the result of long or successive occupations on a site and if they are the result of voluntary creative acts or not. In any case, it is clear that they are islands of surprising fertility among the tropical acid and poor soils. It is difficult to believe that this remarkable quality has been not noticed by the first inhabitants of Amazon, although it is still complicated to prove that these soils have been used for the agriculture by pre-Columbian Amerindians.

Finally, pre-Columbian inhabitants not only modified the topsoil and the nature of the soil but also the morphology of the surface in many places. Amerindians dug, turned around, transported, lifted, and built thousands of cubic meters of earth, transforming the modeling of its territory more or less in a radical way. A net of permanent dug routes, channels, and ditches crossed pre-Columbian Amazonia. Moreover, built causeways connected artificial mounds, and dikes delimited pools and reservoirs. Finally, various plants were cultivated on raised fields with a large variety of forms, dimensions, and arrangements (Rostain 2012).

Indeed, the discovery of immense archaeological settlements and the revelation of complex societies by the new generation of archaeologists working in the Amazon since the 1980s provoked radical revision of our assumptions about pre-Columbian peoples. We became aware of the size and density of the earthworks from the Llanos de Moxos of Mojos, Bolivia (Erickson 1993). Similarly, contemporaneous archaeological works at the Marajoara mounds of Marajó Island revealed that the existence of complex societies in the region was not the result of an ancient migration from the Andes (Meggers and Evans 1957) but rather the product of a long-term, local development (Roosevelt 1991). However, if recent investigations revealed the importance of landscape management by pre-Columbian societies, it must be stressed that such human impact has been heterogeneous and did not affect the entire Amazonia but only specific areas (Bush and Silman 2007; Barlow et al. 2012; Balée 2013).

Recently, Eduardo Neves and James Petersen discovered and studied several enormous sites along the Middle Amazon, which often contained settlement mounds (Lima et al. 2006; Neves and Petersen 2006).

At the same time, in the Upper Xingu of Brazil, Michael Heckenberger (2005; Heckenberger et al. 2008) excavated the site of Kuhikugu, which major development occurred around 1510 AD. With a surface area of 50 ha, it is the largest residential site of the region. Its organization is similar to that of the nearby modern Kayapó villages, consisting of a ring-shaped settlement oriented around an immense central plaza. In the archaeological site, the large communal houses were located on the periphery and were protected by two rows of ditches. Very wide roads originated from the village in a radial pattern to connect it with secondary sites. A variety of fairly large earthworks marked the landscape: docks, bridge foundations, etc. The territory as a whole was organized in a system of principal centers and secondary settlements, indicating the existence of a stratified society. Today, the indigenous populations of the Upper Xingu still live in this type of large, ring-shaped village, connected to one another by wide, straight roads.

Pre-Columbian earthworks are varied, but they share three principal functions. The first one is for settlement on artificial mounds, which includes funerary functions since burials have frequently

been discovered in these residential mounds, as well as ceremonial uses. Certain mounds were dedicated solely to funerary functions, such as the San Jorge basin of Colombia (Plazas and Falchetti de Saenz 1981). The second function is for defense, through ditches excavated on the periphery of settlements. The third function is agriculture on raised fields. Such pre-Columbian earthworks still can be observed in the Guianas (Rostain 2010), particularly along the coast.

The Context

The Guiana Shield forms an "island" of approximately 1,800,000 km^2 bordered on all its periphery by water: the Amazon and Negro rivers, the Casiquiare Canal, the Orinoco River, and the Atlantic Ocean (Fig. 1). Today, this region includes five coastal countries: Venezuelan Guiana, Guyana, Suriname, French Guiana, and Amapá in Brazil. As in the rest of Amazonian rainforest, many different natural environments can be distinguished. However, there are three main landscapes that had strong influence on the pre-Columbian peopling: the grassy savannas in the center, the inland rainforest covering most of the area, and the coastal swampy plain.

The pre-Columbian cultural evolution of the Guianas is divided into four main phases that represent different food procurement strategies: nomadic hunter-gatherers from ca. 11,000 years BP, semisedentary fisher-gatherers from 6,000 years BP, the first farmers employing slash-and-burn agriculture and agroforestry from 3,000 years BP, and raised-field farmers employing permanent agriculture from 1,700 years BP.

It is very probable that several human groups using these different strategies lived simultaneously. However, a clear boundary can be seen along the coast, marked by the Cayenne Island in modern French Guiana, few centuries after the beginning the Christian era. Southeastern communities, connected with cultural traditions of the Lower Amazon, continued the technique of slash-and-burn agriculture and small-scale food procurement strategies up to the arrival of the Europeans. At the same time, Western populations, derived from the Barrancoid and Arauquinoid traditions of the Orinoco Valley, intensified their agriculture using the raised-field technique and transforming enormous surfaces of flooding savannas and swamps. Most of these different agricultures disappeared from 1500 AD because of the effects of the European Conquest.

The human history of the Guianas began 13,000–10,000 years ago, during a dry and cold climatic phase. Paleolithic hunter-gatherers quickly began to experiment plants and to induce change in flora composition and distribution. However, major human impacts on the tropical rainforest occurred some millennia later when agriculturalists transformed soil composition and morphology of the surface of the ground creating coupled human environmental systems.

Process of domestication and incipient agriculture differ notably in the tropics than in temperate regions of the globe. While most of the Neolithic cradles of the northern hemisphere domesticated one major cereal crop and generally developed one single agricultural technique, Amazonia used tens of domesticated and semidomesticated different plants. At the same time, indigenous invented a wide variety of efficient agricultural systems, including agroforestry, slash and burn, alluvial culture, raised fields, etc. Moreover, certain plants were not domesticated but actively managed or cultivated, especially many species of palms. In various cases, such agricultural techniques were coupled with elaborated management of faunal exploitation, as ponds or parks. In fact, scientists agree today to recognize a large set of pre-Columbian strategies of animal, faunal, and habitat management that is considered as a true "domestication of landscape." Natives took advantage of each environmental quality of their biotope, and, when it was not sufficient, they created ingenious systems to improve them. One fascinating characteristic of these solutions is the systematic reconstitution of an equilibrated habitat after exploitation. They ran and transformed their surroundings without destroying it, but stimulating regeneration.

The agricultural intensification is dated of the beginning of the Christian era with the

increasing population and the multiplication of settlements all over the Guianas and, more generally, Amazonia. For instance, Amazonian dark earth (or *terra preta*) agriculture is a spectacular system that used fertility induced by the intense transformation of the earth provoked by long and important human occupation in the same place. Another spectacular agricultural system has been the raised fields in swamp or seasonally flooded areas that began to expanse along the Guianas coast and the Venezuelan Llanos from 500 AD. Still today, impressive extended monumental heritage of this pre-Columbian raised-field agriculture can be observed, especially from air, in the flooded savannas of the Guianas (Rostain 1991). The most prominent features of these pre-Columbian agricultural systems are, in first place, the durability of their effects and the permanence of their traces up to now and, in second place, that they resulted from a coupled action of culture and nature, proving the intimate marriage between indigenous intervention and environmental activity in Amazonia (McKey et al. 2010).

In the Guianas, like in other places in Amazonia, pre-Columbian populations greatly modified their landscapes, particularly those areas that were otherwise not well adapted to agriculture. The goal was to control excess water through drainage systems. In the Guianas, raised fields were elongated, square, or round, but the internal organization of these complexes can vary considerably. The principal difference among these systems is whether they articulate with rivers, standing water, or periodically flooded spaces.

Raised Fields

The most impressive pre-Columbian landscape modifications in the Guianas can be observed in the coastal plain that runs on 1,600 km from the Amazon Mouth up to the Orinoco Delta. Thousands of raised fields have been built by pre-Columbian inhabitants on a portion of 600 km long, between the Berbice River in Guyana and the Cayenne Island in French Guiana (Fig. 1). There is a great variability of shapes and distribution of these raised fields. Nevertheless, the diversity of agricultural structures does not appear random but is rather the result of careful strategies adapted to the local hydrology, chronology of construction, and the available technology. The form and size of raised fields would be thus influenced by cultural and technological criteria, which thereby justify the development of a general classification scheme. Four major types of raised fields can be proposed, based principally on size and to a lesser extent on morphology: elongated raised fields, large mounds, medium mounds, and small mounds:

1. Elongated raised fields vary in appearance from place to place, with dominant types apparent in different countries. In French Guiana and eastern Suriname, they can range from 1 to 7 m wide, 5 to 30 m long (although they are rarely longer than 10 m), and 50 cm to 1 m high. They are generally rectangular, although occasionally oval. While sometimes located in flooded depressions, they are more often located along the interface between flooded zones and sand bars. Their distribution, whether parallel or perpendicular to the slope, depends on their elevation. Raised fields at the foot of Quaternary sand bars follow the slope to facilitate drainage. Those located in the nonseasonally flooded zone on top of the sand bars are arranged perpendicular to the slope, to optimize water retention. In the year-round seasonally flooded zones, they are organized parallel to one another, forming a checkerboard that facilitates irrigation.

   In western Suriname, one finds regular and irregular complexes (Boomert 1976). The former exist in various forms: round, oval, square, and rectangular. They measure 3–4 m wide and 4–30 m long, while the canals between the mounds measure 50–100 cm wide. They are arranged around habitation mounds in the marshes of the recent coastal plain or close to the sand ridges to the east. Irregular complexes are rounded or oval rectangles measuring 4–5 m wide and anywhere from 8 to 140 m long, with 30 m being the average. The canals between the mounds

are narrower, 1–2 m wide, but erosion has partially destroyed them. They are distributed in compact groups of two to 15 mounds in marshy areas of the recent coastal plain or below the sand ridges. Raised fields are generally smaller and shorter on the sand ridges than on the coastal plain. On the western part of the coast of Suriname, raised fields can be differentiated chronologically based on their morphology and their association with Barrancoid or Arauquinoid habitation mounds (Boomert 1980). Regular (quadrangular) raised fields are associated with Wageningen-1 and 2, Buckleburg-1 and 2, and de Burnside habitation mounds. Irregular raised fields are generally near Hertenrits and Wageningen-1 mounds, indicating an Arauquinoid association (650–1200 AD).

Several complexes of elongated raised fields in eastern Guyana are visible in aerial view. Generally, these constructions are poorly documented, but those observed are most often distributed perpendicular to a river. Close to Fort Nassau, along the Berbice River, George Simon (cited in Plew 2005) recorded 787 rectangular raised fields that measure 1.7–6.9 m wide, 5–8.2 m long, and 50 cm to 1.7 m high. It is likely that other such complexes, associated with habitation mounds, exist along both sides of the Canje and Berbice Rivers.

2. Large mounds vary in diameter from 2 to 6 m and in height from 50 cm to 1 m (only rarely 2 m high). In French Guiana, they are generally rounded near Kourou and quadrangular (although eroded) around the Maillard Savanna to the east. Some are oval, rectangular, or even polygonal, such as in the Iracoubo sector. The largest mounds are generally located in the most inundated areas, their size diminishing progressively with their distance from the seasonally flooded zone. They tend to be arranged in a tight gridded pattern, except for in Guyana, where the large round mounds are widely spaced. They are clearly visible in aerial photographs.
3. Medium mounds are round or square (more rarely rectangular). They measure 1.5–2 m in diameter and 30–50 high. They are organized either in groups or distributed in a checkerboard pattern. They form tight groups when located in forested settings and are difficult to detect from aerial photographs alone. These mounds are often very eroded but likely are identical to the intact mounds that are located in marshy zones.
4. Small mounds are almost always round, only rarely square. They measure 30–150 cm in diameter and 20–30 cm high. They are found on the edges of sand bars or on savannas that are slightly seasonally flooded but are completely dry in August. They are barely visible on aerial photographs at 1:10000 scale and are detected though pedestrian survey.

Large and medium mounds are the most common types; small mounds are the rarest (or perhaps only the most difficult to detect). Elongated raised fields represent an adaptation to specific geomorphological conditions. In most cases, the complexes are made up of an assortment of different types of mounds. This mixing is not accidental. Stereoscopic interpretation of aerial views suggests an intricate engineering at work, addressing multiple factors and well adapted to local conditions.

Multiple survey methods (stereoscopic interpretation of aerial photographs and aerial reconnaissance combined with pedestrian survey) have been conducted by the author in 1989–1991 and 2004–2010 to produce a precise map of pre-Columbian structures on a 200 km stretch of coast in French Guiana. On the basis of this cartography, it has been calculated that raised field cover 2,856 ha in French Guiana. However, in view of multiple destructive factors, it is reasonable to assume that a portion of the pre-Columbian constructions of French Guiana has disappeared and that the extent of territory transformed by indigenous peoples was greater prior to the Conquest.

Similar mapping work was carried out at a larger scale from 2006 to 2008 by the Dutch forester Frans Bubberman along the coast of Suriname (Rostain 2012). Agricultural constructions are less frequently recorded over a great deal of this coast because they are hidden by colonial

polders. However, it is likely that raised fields were equally common as in French Guiana before the Conquest. Combining the ensemble of mapping data available across these regions, it is possible to locate the raised fields of Guiana, from Cayenne (French Guiana) up to the Corantijn River (Suriname), a territory that covers 586 km. The only portion that is currently without data is eastern Guyana, consisting of at least 40 km bordered by the Berbice River.

Form and organization of raised-field complexes vary through time and space. The variability of raised fields in the Guianas is tied to cultural, chronological, and technological differences. Differences in local hydrological and edaphic factors also play a role. In French Guiana and Suriname, raised fields are not distributed along rivers, unlike the elongated raised fields of Guyana and Venezuela. Rather, they are constructed in coastal savannas, where they are organized in groups or grids between the marshes and sand formations. Five principal organization schemas are defined for the Guianas, each reflecting the level and degree of flooding, as well as the local topography:

Agricultural and Social Earthworks in the Guianas, Fig. 2 Raised fields in a flooded area, Maillard Savanna, French Guiana. (Photo by S. Rostain)

1. Permanently flooded zones are frequently characterized by large constructions. These are elongated raised fields or large mounds, arranged in a grid pattern (Fig. 2). Such complexes have been recorded in permanently flooded depression in the Macouria and Awala sectors of French Guiana, as well as in eastern Suriname.
2. Seasonally flooded banks along rivers were cultivated in western Guyana. Parallel groups of elongated raised fields are arranged perpendicularly or in chevron patterns along rivers (Fig. 3). They appear to function more often for irrigation than drainage. These structures are the most common type in South America (the most spectacular examples are along the San Jorge River in Colombia) but can also be found in Guyana, although only in the Berbice and Canje basins.
3. Thalwegs are the preferred location for constructing raised fields because they provide highly concentrated fertile soils. They have been almost completely modified throughout the Guianas coast. Medium mounds are the type most commonly found on thalwegs (Fig. 4). These mounds follow the natural line of the thalweg and are distributed in sinuous formations across the landscape. They are abundant in French Guiana and the preferred location for building raised fields around artificial habitation mounds in western Suriname.
4. The edges of sand bars are another important location for raised field construction because the slope allows for adaptations to changing flood levels over the course of the year. These zones are marked by the most complex examples of agricultural distribution; each mound is individually adapted to local hydrologic conditions (Fig. 5). Thus, the shape and size of raised fields vary according to their location. This type of organization is common in French Guiana, particularly in the Kourou sector but also in eastern Suriname.

5. The seasonally flooded savannas, completely dry in August, are the largest spaces cultivated by indigenous peoples. Almost the entire surface is modified; only the highest areas and the sandiest zones are left untouched (Fig. 6). It is also notable that the most seasonally flooded areas were not utilized. Across these vast, flat surfaces, raised fields are very similar and located closely together. Only in eastern Guyana are large, widely spaced mounds reported. But doubts regarding whether they are of anthropogenic origin remain unresolved. Elsewhere, the mounds are generally medium in size, although large and small mounds also may occur.

Thus, the morphology and the distribution of raised fields are linked to topography and water levels, with variability possible within a single complex. Furthermore, the mounds sometimes form homogeneous and independent groups extending on half hectare each. Along the coast of the Guianas, some sectors are dominated by specific types of mound complexes. From west to east, seven principal modes of organization have been distinguished (Fig. 1). Cultural or geographic reasons for these differences are not always apparent. Nevertheless, it seems that each sector corresponds to a specific archaeological culture, associated to a specific environment:

1. Berbice sector: along the eastern part of the coast of Guyana, the dominant pattern is a series of elongated raised fields oriented perpendicular to rivers. Also common are very large mounds, up to 2 m high, widely

spaced across the seasonally flooded savannas. Perhaps, pertaining to the Barrancoid period, they would represent a different chronological phase.

2. Hertenrits sector: in the recent coastal plain of western Suriname, complexes of elongated raised fields of varying sizes follow the contour of the thalwegs. The raised fields are either arranged in small concentrations or distributed in a disordered manner.
3. Barbakoeba sector: in the east of the country, from the Suriname River to the Maroni, raised fields (large or medium) are principally distributed around Quaternary sand formations.
4. Awala sector: both banks of the Maroni and also the Lower Mana, these consist of flooded depressions that have been modified by humans by the construction of large mounds or elongated raised fields arranged in grids.
5. Iracoubo sector: between the Organabo and Sinnamary Rivers of French Guiana, these are principally seasonally flooded savannas covered by large and medium mounds. There are also raised fields on the southern thalwegs, south of the route nationale no. 1 (national road that runs east-west along the coast).
6. Kourou sector: from the Sinnamary to the Macouria, elongated raised fields and mounds

tend to be fairly randomly distributed along the contours of sand bars. South of the coastal plain, below route nationale no. 1, thalwegs are the preferred location and are generally associated with large and medium mounds.

7. Macouria sector: from the Macouria River to the Cayenne Island, although there is some preference for thalwegs, the savanna and flooded depressions are also used. The mounds are large and medium in size and tend to be square.

The coastal stretch between the Hertenrits and Barbakoeba sectors is named Kwatta, where few raised fields have been detected. It is assumed that indigenous peoples cultivated without using the raised field technique the region's sandy shell ridges that are supposed more fertile than the coastal savannas.

Structures are generally arranged geometrically in a well-defined grid (although less symmetrical examples are occasionally noted). Our knowledge of the distribution of pre-Columbian earthworks on the coast of Guiana is still incomplete but indicates that a great deal of the seasonally flooded zones to the west of Cayenne was transformed by pre-Columbian peoples.

The elevation of the fields permits successful farming of land that has low agricultural fertility and is subject to periodic, prolonged flooding. The ancient coastal plain of the Guianas is largely composed of marshes, unsuitable for cultivation without modification. The solution adopted by indigenous groups was to construct mounds that reached above the highest flood level. This technique combines two principal functions: drainage of the soil and the concentration of fertile material.

The removal of soil from the matrix for constructing the mounds also produced drainage canals between the raised fields. The canals, in addition to their primary function of drainage, permit the elimination of harmful gases that limit root growth. This practice considerably reduces the risk of rot for the crops, particularly tubers.

The construction of raised fields in the Guianas corresponded to a period of extremely humid climatic conditions. Between 1300 and 800 years BP, intense rains provoked flooding in the Amazonian lowlands (Colinvaux et al. 1985; Colinvaux 1989). Pollen analysis carried out on the artificial habitation mounds of western Suriname demonstrates that they were built during periods of freshwater flooding (Versteeg 1985). The elevation of the surface of habitation mounds well above the present day high flood stage for the region, and that of Marajó Island, may also be evidence that the flood level was higher during this past period. Drained land would therefore have been less available in the past. These conditions likely led to the development of raised field techniques, at least in Suriname.

The second function of elevating mounds is to improve the structure of the soil. The clay soils of the marshes on the coastal plain are not well-suited for farming, but the construction of mounds concentrates the highest quality earth for planting. This technique also aerates the soil, which improves plant growth due to deeper penetration of roots and tubers. Restoring eroded mounds with sediment from between the fields rejuvenates the cultivated soil. Nevertheless, the application of fertilizers is important for increasing productivity. In the eighteenth century, Father Juan Gumilla (1963) observed indigenous peoples constructing raised fields along the Middle Orinoco, in Venezuela. He noted that they included dried vegetal material in the mounds. This same method of fertilization is still practiced by modern Brazilian and Haitian farmers who cultivate on raised fields. It seems that this technique could have been also practiced by pre-Columbian farmers. Recovery of phytoliths characteristic of maize rachis, stems, and leaves in raised fields in the Grand Macoua savanna indicates that crop remains were incorporated in the mounds as fertilizer (McKey et al. 2010; Iriarte et al. 2010).

Pedologists and archaeobotanists carried out sampling and measurements on the Grand Macoua and Organabo savannas in French Guiana (McKey et al. 2010). A comparison of phytolith assemblages and variations in the levels of stable carbon isotopes provides insight into the history of the landscape. Samples were collected from a stratigraphic column to a depth of 70 cm below

surface. The phytolith spectrum at different depths provides an image of the dominant vegetal community at different points through time, with the deeper deposits older than the deposits closer to the surface. The analysis reveals two trends that evolved in a parallel manner. The first trend shows the increase of the relative proportion of grasses of the subfamily Panicoideae from the lower clay level to the upper, more organic level and the decrease of the proportion of sedges (Cyperaceae) and herbaceous dicotyledons moving from the lowest level to the surface. The second trend indicates fairly homogeneous vegetation in the lower levels transitioning to more differentiated vegetation between the mounds (grasses) and the matrix close to the surface (Cyperaceae). These results are confirmed by isotopic analysis of the organic material in the soil, which shows a transition from a homogeneous isotopic signature in the lower levels (indicating a higher proportion of C3 plants) to a heterogeneous signature near the surface, with the mounds displaying a strong signal of the contribution of C4 plants (the greatest contributor being the grasses of the Panicoideae subfamily) and the matrix dominated by C3 plants (i.e., herbaceous plants such as *Heliconia*, Marantaceae (arrow root family) and, a few grass species, along with most sedges (Cyperaceae). The modern vegetation at the site demonstrates the same pattern, with a stronger proportion of C4 plants on the mounds and C3 plants in the matrix. The change in the vegetation communities can be interpreted as the result of a change from naturally flat and flooded savanna to a savanna scattered with mounds, where heterogeneity was introduced by humans (Renard et al. 2011).

The principal physical constraint is access to water and control of its circulation. Indigenous people deliberately located their mound complexes between low-lying areas and sand bars. Nevertheless, this precaution did not always protect the mounds from flooding, and it was sometimes necessary to surround certain groups of fields with drainage canals. The distribution of elongated raised fields in grids also reflects a concern for water control. In several complexes, the fields follow the downhill slope of the sand bars, likely to facilitate drainage. Conversely, the upstream elongated raised fields (in a less humid environment) are distributed perpendicular to the slope to favor water retention.

The mounds serve a double function. First, they protect plants from flooding because they elevate the planting surface above the flood level, and they facilitate drainage because the soil cannot absorb all of the rainfall during the wet season. Second, they concentrate organic material (residues of harvests and weeds) for the more demanding crops, such as maize or yams. The mounds also permit aeration of the soil. Physical and chemical constraints could be easily overcome by minimal fertilization and efficient water control. In any case, locating raised fields on the edge of flooded, seasonally flooded, and dry zones reflects a conscious decision-making by indigenous peoples. Finally, compared with highland slash-and-burn cultivation, it seems that raised fields allow for better regeneration of soils and are more sustainable over the long term.

Dating raised fields directly is challenging because they are constructed from material transported from surrounding areas and thus contain little datable material. The anthropogenic remains that are sometimes recovered from the mounds are generally not useful because their presence does not necessarily correspond to the period of utilization. In addition, they may also consist of material that predates the mound but was brought there during its construction, or conversely, material abandoned on the mound more recently. While these possibilities may be unlikely because the seasonally flooded savannas were little exploited prior to the pre-Columbian earthworks and generally ignored by European colonists, they cannot be dismissed.

There are several indices for deductive dating. The young coastal plain of western Suriname was almost never used by Amerindians, Europeans, or Creoles from the Conquest until the 1950s. Therefore, the earthworks found there are most likely of pre-Columbian origin. Furthermore, the raised fields of this region have always been organized around artificial residential mounds that are clearly indigenous and associated with the Barrancoid or Arauquinoid periods (300–1250 AD).

The discovery of a wooden shovel in the peat of the Arauquinoid site Prins Bernhard Polder, dated to the thirteenth century AD, supports this chronological association. This tool, perfectly adapted for excavating clay to construct mounds, was no doubt abandoned during the period of construction and thus represents a useful chronological marker (Fig. 7). Elsewhere in the tropical lowlands of South America, mound complexes are also associated with constructions that are clearly pre-Columbian and located in areas recently taken over by colonists. Nevertheless, those circumstances represent only indirect evidence of the antiquity of the raised fields and are insufficient for secure dating.

Agricultural and Social Earthworks in the Guianas, Fig. 7 Wooden shovels: at left, archaeological specimen from western Suriname, dated 1240–1280 AD; at right, Ashuslay shovel from Paraguay, at the beginning of the twentieth century. (Photos by S. Rostain and E. Nordenskiöld 1929)

The only sure dates on Guianas raised fields have been obtained in French Guiana. Organic material extracted from the tops of the paleosols buried under the mound complexes of Bois Diable and K-VIII, west of Kourou, has been dated using ^{14}C. The ages obtained are, respectively, 760 ± 40 BP (calibrated 670–700 BP) and 1010 ± 40 BP (calibrated 920–950 BP) (McKey et al. 2010). Other ages are 1060 ± 30 BP (calibrated 898–1022 AD) in Bois Diable and 620 ± 30 BP (calibrated 1289–1404 AD) in Matiti savanna. These dates correspond to those obtained from the sites of Barbakoeba on the west coast of French Guiana and from the eastern coast of Suriname. It is therefore reasonable to attribute the construction of the raised fields to the Barbakoeba groups that inhabited the sand ridges bordering the mound complexes (Figs. 8 and 9).

Canals, Causeways, and Mounds

While raised fields constitute the principal landscape modification employed by indigenous peoples, other transformations to the environment are known. Canals were frequently associated with agricultural constructions in order to improve drainage. However, not all constructions served an agricultural function. Streams were diverted and canals excavated to facilitate their circulation. Roads were elevated to cross safely flooded areas. Finally, enormous clay mounds were constructed as foundations for villages.

Stereoscopic interpretation reveals a tremendous number of excavated features, both natural and anthropogenic. These consist of irregular lines created by water flow or rectilinear canals. It is sometimes difficult to determine which are anthropogenic in origin because these earthworks can be easily confused with features caused by natural runoff. Due to their horizontality, the seasonally flooded savannas are characterized by a dense and disordered hydrologic pattern. However, these natural networks are too random to aid with drainage of the raised fields. Thus, it was necessary for indigenous peoples to excavate ditches to redirect excess water, which they often accomplished by simply modifying segments of

Agricultural and Social Earthworks in the Guianas, Fig. 9 Hertenrits territory in western Suriname: the red marks are artificial mounds, the yellow areas are raised fields, the brown lines are dug pathways, and the blue lines are small rivers, sometimes deviated by pre-Columbian inhabitants. (Drawing by S. Rostain)

the existing natural channels. In other cases, they excavated straight and wide drainage canals. This latter technique was also practiced by European colonists, who constructed long canals for the polders but also as routes for communication. Leroy Canal, which stretches for almost 11 km to the west of Kourou, is an example of these colonial constructions. It is therefore often difficult to identify with certainty the nature and origin of the drainage routes observed. Four types of hydraulic modifications are distinguished: enclosed ditches, canals, pools, and dug paths:

1. Enclosed ditches are linear features that follow an irregular course, perpendicular to the natural flow of water. They often connect two areas of high ground and enclose a group of raised fields. These small, artificial features measure from 1 to 2 m wide and several dozen meters long. They provide protection from flooding during the rainy season. They are relatively narrow and shallow at their extremities but often form a basin at the center point. These ditches therefore not only divert excess water in the rainy season, but they also provide a reservoir of water in the dry season.
2. Canals are rectilinear ditches, wider and deeper than enclosed ditches. They measure between

50 and 600 m long and between 2 and 5 m wide. They often enclose a seasonally flooded space and appear to control its drainage. Beyond their drainage function, the ditches and canals can also serve as reservoirs of water during the dry season and as permanent fishponds. Nevertheless, this type of canal is relatively rare. In French Guiana, in the Kourou sector, they are more frequent to the south of route nationale no.1 than to its north. This distribution is probably due to greater problems with drainage in the southern zone, which is elevated slightly higher than the northern plain. Canals are less common toward the marine shore, where they would be counterproductive because the clay soils become impermeable once they are saturated. Also, the construction of a dense drainage network could provoke a rise of brackish water, which would irreversibly render the soil uncultivable.

Raised fields are constructed and organized based on consideration of the seasonal levels and circulation of water. Ditches were constructed to control water flow.

3. Pools are excavated areas that function to conserve water and/or for pisciculture. They are not formally recorded in French Guiana but occur to the east of Suriname (Boomert 1976).
4. Dug paths and the channeling of streams are similar to canals, but they are much smaller in their dimensions, and their usage is radically different. Rather than being used for agriculture, they facilitate circulation. The most notable example is associated with the artificial settlement mounds of Hertenrits, where a network of these linear furrows forms a grid 10 km in diameter (Fig. 10). Indigenous people have drastically changed the course of small natural streams that cut across the plain. Most of the time, this involves altering the course of water flow to render it more rectilinear. In other cases, two existing creeks are linked by a passage. Completely human-made channels occur as well. The Hertenrits mound is surrounded by a large spider web pattern of dug paths. Some lengthen the course of natural streams, while others run parallel to creeks. Many extend out from residential mounds and link with raised field complexes or secondary domestic mounds. These sunken paths serve a double function. During the dry season, they mark paths to arrive at a specific location. These ancient networks resemble those associated with modern indigenous villages today. During the rainy season, when the plain is flooded, the same paths can be used as canals for pirogues. The flooding is not very deep across the plain and boats thus risk running aground. The sunken paths serve as canals that permit the navigator to direct his boat safely across the landscape.

Agricultural and Social Earthworks in the Guianas, Fig. 10 Burnt raised fields by modern fire, Maillard Savanna, French Guiana. (Photo by S. Rostain)

In eastern Suriname, the flow of creeks has also been modified to aid the circulation of boats. Across the Guianas, canal reaches are common on the bends of rivers. These are canals that pass through the forest to facilitate passage of pirogues and shorten the overall route by not requiring the craft to follow the longer, natural course of the river. In some cases, the shallow canals were constructed to connect two points of the river. Therefore, it is possible that some of the canals that connect higher parts of the coastal plain of Guiana served as routes for pirogues.

In French Guiana, two ancient human-constructed canals cross the road no. 22 linking Mana to Awala (Cornette 1987). They pass through the chenier on which the road is constructed and enter the marshes on both sides of the sand formation. The first canal cuts the road at 8.6 km east of the village. Its length is estimated at 2 km, but it is not perfectly straight because there are two slight changes of its orientation from 10° to 30° east. At its intersection with the road, it measures 21.4 m wide at the top of its walls (a slope of 25° to the northwest and 31° to the southeast). It is 4 m at its base and its maximum depth is 3.15 m. It has a concave section and a relatively flat base. When it enters the forest to the south, the width of the canal diminishes to an average of 8 m. The second canal, 12 m wide, crosses the road perpendicularly at 5.2 km from the first and is located several dozen meters east of raised fields. Another canal, 5 m wide and approximately 1 m deep, is noted close to the ancient Kali'na village of Coswine. According to the indigenous people of Awala, these canals were related to the site of *Nieku dupo* ("where the poison root for fishing is found"), which today no longer exists. (The *nivrée* is fishing with poison using macerated plant material having bioactive principles that paralyze the gills of fish, causing them to rise to the surface clumsily, from several vines in the Sapindaceae (soapberry) and Fabaceae (bean) families or from two cultivated shrubs, one in the Fabaceae family and the other in the Asteraceae (sunflower) family (William Balée, 2012, personal communication).)The myth of *Sibalalimbo* ("the man dressed in iron") tells that the Kali'na of this village had dug sunken paths to quickly assemble their warriors during conflicts with the English during the Colonial period.

The inverse of the dug paths is the raised paths or causeways. Stereoscopic interpretation has identified artificial earthen levees in several highly flooded areas of French Guiana, close to the modern shore. Some constructions of this type have been found in French Guiana. These levees cross the marshes, perpendicular to the shoreline. Three link together two cheniers, while the final departs from a chenier and ends in the mangroves along the shore. They measure 430 m long and 8 m wide, 330 m long and 5 m wide, and 450 m long and 3 m wide.

The most remarkable earthworks are the habitation mounds. There are almost no cheniers in the recent coastal plain of western Suriname and eastern Guyana. Thus, indigenous peoples had to adapt in order to build settlements. Due to the lack of sufficient dry land for their villages, they constructed immense, circular clay mounds above the flood level. Arauquinoid populations were accustomed to wetland environments and skilled in their modification. Several artificial mounds and other earthworks are found within the Arauquinoid sphere of influence in the Venezuelan *llanos* (Redmond and Spencer 2007). Versteeg's (1985) doctoral thesis at the University of Leiden in the Netherlands presented a study of mounds in western Suriname. In Suriname, of the 15 potentially anthropogenic mounds recorded by van der Heide (1973), seven are clearly ancient indigenous villages, two do not contain archaeological materials, two were circular mounds produced by the growth of *Avicennia* mangroves, and the remaining four were not visited (Versteeg 1985). The mounds in eastern Guyana are less well-known due to a lack of archaeological work, but the majority of them appear to belong to the Abary culture, a Barrancoid tradition, defined by Clifford Evans and Betty Meggers (1960).

The Barrancoid peoples were the first to construct settlement mounds in Guiana during the first few centuries of the Christian era. Analysis and dating of pollen from peat layers indicate that between 300 and 1000 AD, freshwater conditions prevailed on the western plain of Suriname (Versteeg 1985). It was at this time that

Barrancoid groups began mound construction. The mounds were constructed in stages, as is evidenced by the succession of light and dark layers in the stratigraphy. The former correspond to the foundational fill, while the latter represent the actual remains of the occupation.

- Buckleburg-1 is a circular mound that measures 139 × 137 m in diameter. Its mean altitude is 2.7 m asl or 1.5–1.9 m above the level of the surrounding marsh. Humans arrived in the area around 1835 BP, and construction began at 1735 BP. The mound was abandoned by the Barrancoid people shortly after 1315 ± 55 BP.
- Buckleburg-2 is slightly larger and taller than Buckleburg-1, located 2.1 km to the west/southwest. The two sites share similar ceramics. Furthermore, the two mounds are built along the same river.
- Wageningen-1 is a slightly oval mound that measures 130 × 100 m in diameter and has an altitude of 2.25 m asl or close to 1 m above the level of the marsh. Its construction began at 1315 ± 20 BP and its occupants left after 1130 ± 45 BP. The ceramic style is defined as Early Hertenrits, which corresponds to the Early Arauquinoid period.
- Wageningen-2 is a small oval mound located 1.6 km southeast of Hertenrits and is associated with this culture. It measures 60 × 40 m in diameter and is 40–50 cm high.
- Wageningen-3 is situated 2.8 km to the northwest of Hertenrits. It measures 80 × 60 m in diameter and 40 cm high. Like the two previous mounds, it is located in the territorial network of the Hertenrits culture.
- Burnside is the easternmost mound in the region. Oval in shape, it measures approximately 100 m in diameter and rises 50–75 cm above the level of the marsh. The ceramics collected from the mound are associated with the Hertenrits culture.
- Joanna, on the banks of the Canje River, is the only well-described mound in eastern Guyana (Goodland 1964). Surrounded by a ditch from which the construction material was derived, it measures 90 m in diameter and 2.5 m high.
- Hertenrits, 6 km south of the modern shoreline, is the largest of all the known residential mounds and has the longest occupation. It was named "sandy ridge of the deer" (*hert-en-rits* in Dutch) by the hunters who used it in the past. Oval in shape, it measures between 200 and 320 m in diameter and averages 2.9 m above the level of the marsh (Boomert 1980). The ceramic sherds recovered in the different levels are divided into two successive styles, Early and Late Hertenrits (Versteeg 1985). The mound was inhabited between 1265 BP and 935 ± 35 BP, but the stylistic change at the end of the sequence is interpreted as the result of the arrival of a new influx of population from the Orinoco around 1000–900 BP.

Besides the artificial mounds, often associated with paths and raised fields, as well as reservoirs and fishponds, the other notable earthworks found in the Amazon are the peripheral ditches. To date, they have been found in the east of Guiana and the Upper Amazon.

In French Guiana, east of Suriname and the eastern edges of Amapá, more than 40 sites with peripheral ditches have been reported, but it is probable that many more still are hidden by the forest. The Saramaka call them "crowned mountains." These are generally small hills, close to a river, ringed at the summit by a ditch 3–15 m wide and approximately 1 m deep, generally filled in one, two, or three places to allow crossing. They measure on average 100 m in diameter. Some reach up to 800 m long, 8 m wide, and 5 m deep. In one case, the ditch was carved directly into the rock (Éric Gassies, 2009, personal communication). Sometimes, particularly on the high banks of the river, the ditch only closes a hillfort. Little archaeological work has been carried out on these structures. These sites are particularly frequent in the interior of French Guiana and rare in Amapá and Suriname. They are dated from the beginning of the Christian era to the early Colonial period (sixteenth century).

To the northeast of Suriname, the peripheral ditch of Pondo Kreek-2 was excavated in 1980 (Versteeg 1981). The oval ditch has a diameter of

120 m by 95 m and measures on average 4.2 m wide, with an original depth of 3 m. Surface collections yielded 264 quartz tempered sherds (four of which were painted or 1.5% of the sample) and a quartz polishing stone for ceramics. Three test trenches cut across the ditch produced very little archaeological material (Aad Versteeg, 1994, personal communication). A piece of wood charcoal, collected at 175–180 cm below the base of the ditch, was dated to 1180 ± 70 BP (Versteeg 1981). The exact function of these sites is unknown, but it seems likely that they were fortified villages or ceremonial sites. The thinness of the anthropogenic level and the low percentage of phosphates recorded at Pondo Kreek-2 (Versteeg 1981), as well as the rarity of the archaeological material discovered, do not suggest a long occupation or a permanent settlement.

The ditched hill of Crique Yaou, on the Upper Maroni of French Guiana, excavated in 1992, revealed two archaeological levels and furnished a number of ceramic sherds. The two ^{14}C dates obtained on wood charcoal range between 200 BC and 130 AD. Dating carried out at other ditched hill sites throughout French Guiana have returned ages between the beginning of the Christian Era and the European Conquest (Mazière et al. 1997; Éric Gassies, 2009, personal communication).

The oral tradition of the Wayampi of Oyapock attributes these sites to the ancient Karane, who inhabited villages with defensive structures: "*throughout the region, there were many Kalana. They constructed villages that they protected with ditches two meters wide and one meter deep. Stakes were planted at the bottom. Those who did not know fell in and died. There are still remains of these ditches around the mountains close to Camopi and elsewhere*" (Captain Norbert cited by Grenand 1982: 270). Moreover, at the end of the eighteenth century, on the Inirida tributary of the upper Orinoco, the Puinave (warriors who practiced cannibalism) lived in fortified villages surrounded by ditches filled with poisoned stakes (Dreyfus 1992). At this time, the Wayana villages of French Guiana also presented elaborate defensive systems (Leblond 1813). However, these data are insufficient to prove the military use of pre-Columbian ditched sites. Thus, if the defensive function cannot be discarded, it is more probable that they had a ceremonial use.

Built Landscape

Stereoscopic interpretation, archaeological excavation, and the analysis of the natural and anthropogenic environments of the coast of Guiana have revealed significant impact by pre-Columbian populations on their landscape. These transformations were accompanied by rigorous management of the territory and the organization of many small parcels. Furthermore, the sociopolitical scope of different settlements seems to have varied, with some exercising more power than others.

One of the most significant criteria to determine the existence of chiefdoms is the hierarchization of sites based on their political importance. This aspect has been, to date, little studied in Amazonian archaeology. I have thus attempted to evaluate whether Arauquinoid sites fall into a hierarchical model.

In the floodplain of the Guianese coast, the cheniers offer ideal locations for villages, which are arranged along the length of these sand formations, extending parallel to the coast and connected to one another by paths. While each of these settlements was limited by the narrow width of the sand bars (less than 200 m), they spread over several hundreds of meters, at times, even over many kilometers.

The Barbakoeba site of Sable Blanc, on the western part of the coast of French Guiana, stands out because it combines three different functions: residential, funerary, and agricultural, this last one being located some hundreds of meters south of the settlement. The residential zone is located at the top of the sand bar, with the houses constructed at the highest and driest point. The settlement was arranged in a linear form, punctuated by open spaces, along the length of the chenier. The site is found on the left bank of the Iracoubo River, just south of its mouth. This location corresponds to a recurring model evident for the ancient coastal Arauquinoid villages. The largest sites were systematically located a short distance to the west of a large river and

close to the coast. This is the case for the sites of Bois Diable and Crique Jacques in French Guiana (Rostain 2012) and Kwatta-Tingiholo and Peruvia-2 in Suriname (Versteeg 1985). Access to the ocean was important because the farmers of raised fields also depended heavily on marine resources. The southern slope of the chenier was reserved for funerary activities, and the absence of domestic structures supports this interpretation. Two distinct groups of urns, of similar dimensions, appear in this sector, and it is likely that other such groups can be found in the rainforest farther to the west. These concentrations of urns, simple but with different associations of burials and offerings, could correspond to clans or families within the village. In this case, the cemetery would have been organized very precisely. The drainage canals that cross the necropolis indicate that it was necessary to manage an excess of water at certain times of the year. An artificial embankment 4 m wide and 1.5 m high surrounds the cemetery. It could have served to protect the necropolis from flooding, when the level of the southern marsh rose during the rainy season. In the lowest portions to the south and west, less than a kilometer from the site, there are raised-field complexes that cover the savannas. As in the other sites of Quaternary sand bars, the preferred placement of raised fields is in the marshes south of the settlement.

Thus, Arauquinoid sites of the cheniers demonstrate a specific organization of the settlement and its surroundings. The boundaries are well-defined, and the communities make the most advantage possible of their space. It is difficult to believe that these modifications to the territory resulted from small, independent groups. In addition, notable nonagricultural earthworks were sometimes created. These include embankments, causeways that cross the marshes, and canals or reservoirs (possible fisheries).

These findings are even more convincing for the artificial mound sites of the western part of the coast of Suriname. Pollen samples collected around these constructions show that they were located at the interface of freshwater and saltwater environments (Versteeg 1985). The areas around the mounds were flooded with freshwater at the end of the dry season. This permitted the inhabitants to exploit resources from marine, brackish, and freshwater environments, without going far from their village.

The two Barrancoid artificial mounds of Buckleburg-1 and 2 were constructed on the banks of the same river, about 2 km apart (Versteeg 1985). This likely represents a schema of settlements planned along a river where the principal site is found close to the coast, while the secondary site is established slightly more to the south. It is easy to access one mound from the other, either by boat or on foot.

Hertenrits, in western Suriname, is the most obvious example of carefully defined boundaries. Stereoscopic interpretation of this zone indicates precise management and organization of the territory. The Arauquinoid site of Hertenrits is the largest of the known mounds, covering close to 4 ha. Boomert (1980) estimates that its construction would have required the equivalent of 14,000 loads from a medium size truck. The mound is surrounded by a depression 20–100 m wide, created to extract the clay from which the mound was built. The perimeter is crossed by five canals with traces of moorings, indicating places used as docks. Several channels from water runoff were modified, some perhaps even created by indigenous peoples. The channels that cross the area have often been straightened or lengthened to connect one to another or with the canals. A complex network of straight, shallow canals crosses the landscape.

A number of connections were thus created among the different mounds, the raised-field complexes, and the streams. During the rainy season, the zone was crossed in canoes, while pedestrian paths prevailed in the dry season. Raised-field complexes, consisting of irregular groups of less than 20 elongated fields, occupied the surrounding thalwegs. Two smaller satellite mounds were constructed opposite to one another around Hertenrits. Wageningen-1 is 4 km to the southeast, and Wageningen-3 is 3 km to the northwest. Canals radiating from Hertenrits lead directly to these secondary settlements. The distribution and the connecting features demonstrate that the mounds were contemporaneous. They

were constructed around 650 AD and occupied for several centuries before their abandonment.

The inhabitants of Hertenrits, Wageningen-1, and Wageningen-3 constructed their settlement following a precise model. They carefully divided the territory to take advantage of the full range of resources their biotope offered.

Conclusion

Pre-Columbian populations in Amazonia dug and accumulated earth to build many structures and to adapt their environment to their necessities. Although they offer a biotope rich in various resources, the Amazonian marshy savannas were imperfectly adapted to the needs of their pre-Columbian occupants.

As in forested Amazonia, a late-Holocene expansion – and possibly an intensification – of farming also seems to have occurred in seasonally flooded savannas around the rim of Amazonia in Bolivia, Venezuela, and coastal Guianas (Rostain 2012). To respond to the constraints of these environments, farmers had to develop a monumental agriculture to take advantage of these spaces. This management strategy consisted of constructing mounds above the level of flooding. However, this increase was sometimes insufficient to protect the crops from submersion. Canals, ditches, and levees completed the system to overcome the variability of the water level.

Tens of thousands of hectares of floodplain lands have been developed for agricultural purposes in three major Amazonian regions: the Bolivian llanos to the west, the Venezuelan savannas to the north, and the Guianas marshy coast to the east. Raised fields affect a wide variety of shapes, sizes, and layouts. There is no universal model in elevated fields, each region, and even each site, showing particularities.

There is archaeobotanical evidence (phytoliths and pollen) for cultivation of maize and of squash on raised fields in French Guiana (Iriarte et al. 2010; Charconac and Rostain 2015). Microfossil remains of several other crop plants – yam (*Dioscorea* sp.), sweet potato (*Ipomoea batatas*), yuca (*Manihot esculenta*), and chili pepper (*Capsicum*) – have been found in villages associated with raised-field farmers and were probably also grown on raised fields. Based on the current diet of Amazonian groups, it has often been considered that the diet of pre-Columbian populations must also be based on cassava. Recent researches in the Amazon region, however, shows that this "civilization of manioc" was, in fact, perhaps less preponderant than it is today.

Other archaeobotanical data have been recently obtained in an older settlement in French Guiana based on starch grain analysis (Pagán-Jiménez et al. 2015). In a layer associated to the Late Archaic period, with dates that range from 6090–5740 cal. BP to 4150–3920 cal. BP, of the site of Eva 2, grindstones have been used for the processing of maize (*Zea mays*), sweet potato (*Ipomoea batatas*), chili pepper (*Capsicum* sp.), achira (*Canna* sp.), legumes (Fabaceae), and yams (Dioscoreaceae).

But the indefatigable of pre-Columbian earthmover farmers did not only build these magnificent agricultural chessboards. They also applied their skills to build a multitude of land monuments with various functions. For instance, they erected enormous mounds to settle their villages, to carry out their ceremonies, and to bury their deceased. They also built long roads and dykes, the latter sometimes serving as dams to trap fish. Elsewhere, they dug basins, reservoirs, peripheral ditches, roads, canals, and diverted streams using excavations. A whole hydraulic system therefore came in addition to a set of raised earthworks above the water.

Ceremonial life was also crucial in the pre-Columbian world. There may be too much tendency to see all these various earthworks as having a strict technological and practical purpose, whereas the Amerindian world had an extensive conception of the interaction of man with nature, associating the mythological universe with reality palpable. Some earthworks, for instance, the geoglyphs of Acre State in Brazil, could have served for rituals.

Slash-and-burn agriculture still is largely used in Amazonia by indigenous, so ethnological observations can be made to help to understand this technique. It is not the case with the

raised-field agriculture that has completely disappeared in Amazonia after the European Conquest. As other abandoned agricultural system, its understanding is completely dependent on inferences from the observation of the raised fields themselves and archaeological studies. Such partial data do not authorize to fully evaluate the complete diet of the ancient inhabitants because farming on raised fields was probably only one component of multi-activity subsistence systems (McKey and Rostain 2015). It is necessary to define a wider picture of the sustainability of this raised field, including intensity and productivity, to get a more accurate overview of the ancient indigenous economy.

Because of the absence of similar systems today in South America, a useful path can be to study modern raised-field farmers in other continent. For that reason, Doyle Mckey conducted ethno-ecological research in Africa where many groups still use a similar technic (McKey et al. 2014). Such approach suggested answers to contentious questions about pre-Columbian raised-field agriculture. For example, the integration of fallow periods appears to be a constant.

In sum, agricultural and social earthworks constitute a crucial aspect of the pre-Columbian period in the Guianas. Their study opens wide files of data and conclusions on the ancient inhabitants. Tropical soils can instruct us in many aspects.

Agricultural Practice: Transformation Through Time

Maria C. Bruno
Anthropology & Archaeology Departments, Dickinson College, Carlisle, PA, USA

Introduction

Agricultural production is a dynamic process that evolves out of interactions between plants, animals, the environment, and the food needs of human communities. Through time, agricultural practices changed as farmers developed new techniques to meet demands presented by both their physical and sociopolitical environments. The diversity of past agricultural practices and how they changed through time are reflected in a range of archaeological datasets, from large-scale landscape modifications such as irrigation and field systems to small-scale shifts in plant and animal ecologies. Archaeologists employ a range of methodologies to document the diversity of past agricultural practices and to understand the reasons for change.

A unifying topic in the archaeological study of transformations in agricultural practices through time is that of intensification. Intensification is the increase of agricultural output per unit of land per unit of time (Brookfield 1972). Two aspects of intensification that archaeologists study are (1) documenting the diverse range of intensification practices that past farmers employed and how they changed through time and (2) understanding the reasons why farmers needed to increase production. Both aspects of agricultural production relate to other important aspects of ancient human societies including population size, the environment, and sociopolitical dynamics.

Definition

Around the world, the adoption of agriculture as the primary means of obtaining food came after the initial domestication of plants and animals. In many places, there was a long period of time in which domesticated plants and animals supplemented foraging activities or "low-level food production" (Smith 2001). For a variety of reasons, ranging from climate change to social demands, most of these societies eventually became reliant upon agriculture and foraging became a supplemental practice.

Being a committed agriculturalist requires a fundamental shift in the relationship people have with their environment. In order to assure that a domesticated plant reproduces successfully and in sufficient quantities each year, farmers must learn to manage the dynamic environments in which the plants live and grow. Aside from the crops themselves, farmers must manage inclement weather (hail, frosts, drought), water, soil quality, and competitors (both plants and animals). Each region of the world presents unique characteristics, which have given rise to the diversity of agricultural strategies developed by people through time and space. Despite this diversity, there are common trends seen across the globe as societies became increasingly dependent on agricultural production.

Agricultural Practices

In his book, *Smallholders, Householders: Farm Families and the Ecology of Intensive, Sustainable Agriculture*, anthropologist Robert Netting (1993) provided a useful framework for categorizing the various practices nonindustrial farmers utilize to maintain productive agricultural systems: (1) soil moving and management, (2) water regulation, (3) restoring/increasing soil fertility, (4) diversification of production, and (5) protection of plants from growth-inhibiting competition. Each category is defined and discussed below with some specific examples and a general commentary of how these practices change through time. The types of archaeological evidence and the methods used to study each category are also described.

Soil Moving and Management

A variety of practices involve moving or manipulating the earth in order to support plant growth and control erosion. This can range from simple tilling to more permanent landscape modifications, such as terracing, elevating raised fields, and constructing paddy or pond fields.

In most regions, early agriculture occurred in areas with soils that were loose enough to till with simple tools, such as digging sticks or handheld hoes, including alluvial soils along river floodplains and loess deposits. As agriculture expanded, people often had to modify more difficult terrain in order to make it suitable for planting. For example, in mountainous regions with steep slopes such as the Andes, expansive systems of terraces were constructed. Another major innovation with reference to soil manipulation was the ox-drawn plow. While it initially helped farmers in the Near East farm more efficiently in river valleys, its introduction into Europe permitted expansion of farming into areas with deep, firm soils (Sherratt 1981).

Archaeologists have traditionally studied agricultural practices associated with soil moving and management using aerial and pedestrian survey, as well as analysis of stone, wood, and metal artifacts associated with tilling. Topographic maps and aerial photographs have long been used to document regional field systems. New technologies such as remote sensing with satellite photography and, most recently, airborne light detection and ranging (LiDAR) provide more expansive regional coverage, filters to highlight variations in soil and vegetation, filters to digitally remove obstructive features such as dense vegetation, and in some cases, provide higher resolution of features. For example, the use of LiDAR has revealed extensively terraced hillsides around the Classic Maya site of Caracol that had for centuries been obscured by tropical forest (Chase et al. 2011) (Fig. 1).

Soil manipulation can also be detected in geoarchaeological data sources such as soil profiles, sediment cores, and microstratigraphy (Lehmann et al. 2003). Finally, archaeobotanical datasets can reveal increased soil manipulation through the study of plant species associated with clearance such as a decline in forest species and increase in agricultural weeds.

Agricultural Practice: Transformation Through Time, Fig. 1 LiDAR 2-D image of Ceiba Terminus at Caracol, Belize, showing hundreds of constructed terraces. (From Chase et al. 2011: 394, with permission)

Water Regulation

Farmers utilize a range of strategies to regulate water either to increase its supply or remove it. Water regulation systems that bring and retain water to fields include canal networks, check dams, and pond or paddy fields. Systems that help eliminate water include raised fields or mounded fields.

Early farmers used naturally well-watered areas such as receding floodplains or, in the case of rice, naturally flooded areas. As with soil manipulation, which is in part related to water regulation, when farmers wanted to expand their planting area, they needed to invent ways to transport water from the original source, maintain it, or, in some cases, remove it.

Extensive irrigation systems were developed in arid regions such as Egypt and coastal Peru. Elaborate wet farming systems that involve both canals and water-retaining fields developed throughout East and Southeast Asia and the

Pacific. Throughout the Americas, farmers developed raised-field systems in naturally inundated areas.

Archaeologists use the same range of survey and remote-sensing methods as discussed for soil manipulation and management. There are also innovative uses of archaeobotanical evidence to document the use of irrigation. For example, researchers observed an increase in the size of wheat and barley phytolith skeletons in periods associated with increased irrigation in the Near East and Egypt (Rosen 1994).

Restoring/Increasing Soil Fertility

An important process often associated with intensification is the reduction of the fallow period, or the time in which the field is allowed to rest. The fallow period is crucial for rejuvenating the nutrients in soils; however, if food needs require fields to be more continuously productive, humans can intervene to replenish nutrients and restore soil fertility.

Restoration of soil fertility has been accomplished through a variety of strategies such as crop rotation and adding fertilizer. Rotation involves planting different crops with different soil requirements over successive years. Legume crops are particularly crucial in these systems as they fix nitrogen and can improve soil quality. In Eurasia, legumes are often planted after cereals, and in Central and North America, indigenous farmers planted beans together with maize and squash.

Farmers also add nutrient-rich materials such as animal dung, kitchen or midden ashes, plant litter, and even animal parts to increase fertility. Fertilizing with dung is very common in regions with domesticated animals such as goats, sheep, and cows in Eurasia and camelids in the Andes. Muck from canals and ditches can be excavated and added to the planting field.

In tropical regions, soils tend to be thin and acidic, greatly limiting their natural productivity. These areas are most well known for the use of slash-and-burn or swidden agriculture, where plots of forest vegetation are cut and burned to create ashy, nutrient-rich planting surfaces. Such plots can be used for 4–5 years, but the nutrients are eventually depleted and the area is often overrun with weeds and pests. These plots are abandoned and new ones are cleared. Swidden farming is considered to be an extensive system of production and only able to support relatively small populations.

In the Amazon basin of South America, archaeologists have recently discovered that ancient farmers actually improved soils through a combination of slow burning forests, or creating what is known as a biochar, and possibly adding household waste. This increased the fertility of the soils and these "terra preta do indio" or Amazonian Dark Earths (ADE) are still sought after by modern-day food producers in Brazil. These deposits have been documented and studied by sedimentologists and micromorphologists to understand the practices that formed these unique soils (Lehmann et al. 2003).

When ancient cultivated areas are identified, several geochemical and geoarchaeological methods can help determine if they have been supplemented with fertilizer. There are also several indirect measures that together with other evidence may point to fertilization and soil restoration. These include the presence of manure-producing animals, nitrogen-fixing legumes, or nitrogen-loving (eutrophic) plant species in the archaeological record. Recently, researchers working in the Near East have argued that increased nitrogen levels in human isotopes throughout the Neolithic may reflect fertilization of fields rather than increased meat consumption (Bogaard et al. 2007).

Diversification of Production

Unlike our modern, industrial farming systems that focus on the mass production of a few crops, ancient and subsistence farming systems incorporated a wide range of crops and varieties that were often interplanted and rotated based on local environmental conditions and food needs. They also incorporated domesticated animals and pastoral activities.

The indigenous farming systems that developed and spread throughout the world involved a range of domesticated plant species including seed crops, legumes, tubers, fleshy fruits, and nuts for food and wood, fibers, and resins for industrial uses. For example, in the Andes of South America, ancient farmers grew many varieties of potatoes, as well as other tuber species such as *oca*. They also grew the grain crops quinoa and maize and in some areas leguminous crops such as tarwi and common bean. In more temperate climates, they managed food and spice-producing tree species such as huarango and molle. Additionally, they raised guinea pigs and two species of camelids, llamas and alpacas.

Through time farmers developed many varieties of individual crops and adopted and exchanged new crops for many purposes. Some varieties were selected for their ability to withstand local climatic variations and others were developed to meet diverse culinary tastes and traditions. While there were local developments of crop species and varieties, the spread of different domesticated plant species into new regions also played an important role in changing agricultural practices. In some cases, these new crops were simply integrated into existing cropping systems, such as maize in the Andes. In other cases, the introduced crops eventually replaced some of the indigenous ones, such as in eastern North America where the indigenous crop complex that included sunflower, maygrass, chenopod, and knotweed was eventually replaced by the Mesoamerican tripartite of maize, beans, and squash.

Archaeobotanical remains provide the primary means for studying the composition of past cropping systems. Carbonized, dessicated, or waterlogged macrobotanical remains have provided a great deal of insight into the role of seed crops, legumes, durable fruits, and woods. Tubers and fleshy fruits have been more difficult to study because they often do not preserve, but advances in microbotanical analyses of phytoliths and starch grains are improving our knowledge of these very important species. Finally, analysis of human isotope levels also contributes to the study of cropping regimes, particularly for the introduction and spread of C4 plants, such as maize in the Americas (Hastorf and DeNiro 1985).

Protection

Finally, all farmers must deal with the unwanted plants, animals, and insects that inhabit the fields and present competition or danger to the crops. Pests often increase as farmers intensify agriculture because some species, for example, members of the sunflower and mustard families and some rodents, are especially adapted to the highly disturbed environments in cultivated plots and fields. Additionally, as certain crops are cultivated more frequently for human consumption, they are more readily available to the insects that prefer them.

Several practices can help reduce the number of unwanted species such as plowing or planting toxic or pungent species that deter animals or birds. To remove unwanted plant species, often referred to as weeds, farmers intermittently enter the growing fields and manually remove them. Intercropping diverse crops and varieties, as well as maintaining a crop rotation system, can also serve to reduce pest populations or at least reduce the risk of complete destruction by them. Certain types of wet farming, such as pond and paddy fields, can help reduce the number of weeds and animals in fields. In his study of wet versus dry farming on Futuna Island in the Pacific, Patrick Kirch (1994) found that wet fields required much less work weeding than the dryland farming fields. Fences and earthen barriers also aid in keeping unwanted animals and even other humans away from the crops.

Detecting these types of practices in the archaeological record can be challenging. Fencerows or physical barriers may be encountered in surveyed or excavated field systems. Weedy species are common in archaeobotanical assemblages, particularly in areas where the dung of grazing animals is burned. These assemblages can provide insights into the types of species present in the fields but not necessarily if or how they were removed (Jones et al. 1999). Archaeobotanical studies of crop processing

stages may reveal the removal of weedy species during the grain cleaning process (Hillman 1973). Zooarchaeological studies also provide insight into the animal pests that may have inhabited fields. For example, in the American Southwest, the ubiquity of field and house rodents increased as farming became the primary form of subsistence (Dean 2005). Although farmers do not want these ruderal plant and animal species to destroy their crops, they are often useful resources in their own right. Some weedy plant species can be eaten as greens or used for medicine, while garden hunting can provide an important source of animal food.

These categories provide a general overview of the various strategies farmers employed, how they may have changed through time, and how archaeologists can document them. While understanding this diversity is important, it is also important to understand *why* such practices changed through time.

Historical Background

Theories of Agricultural Change

Archaeologists have long recognized that transformations in agricultural production were linked to other fundamental changes in human prehistory such as the development of complex societies and the founding of cities. V. Gordon Childe (1950) believed that the "Urban Revolution" could only occur once agricultural production was great enough to support non-farming specialists who could produce prestige goods and engage in trade. Julian Steward (1955) and Karl Wittfogel (1956) both argued that the first states emerged in arid regions that required irrigation to expand and intensify agriculture. They believed that a centralized and hierarchical system of governance was required to organize the construction, maintenance, and distribution of water in expansive irrigation systems.

Another factor that early thinkers associated with agricultural production was population. In 1798, Thomas Malthus (2004 [1798]) argued that agricultural production generally could not keep up with population growth. Unless a new technology could be introduced, overpopulation would be checked by famine or war. He did not consider, however, the political or social factors that may have caused such tragedies. This idea was challenged in 1965 by Danish economist Ester Boserup (1965), who, based on observations of nonindustrialized agriculturalists in Africa and Asia, argued that population growth is not limited by available agricultural technologies but that demographic pressure actually stimulates agricultural change. She found that as populations grew, farmers reduced the amount of time they left their fields in fallow and increased their work in the fields by weeding, fertilizing, and plowing in order to make them more productive. In cases where population size fell or pressure was reduced, they would shift back to more extensive land use.

Key Issues/Current Debates

Recent archaeological inquiries and debates have built upon these previous ideas and have attempted to determine which of these various factors, environment, population, and/or sociopolitical dynamics, may have brought about transformations in agricultural production. The main arguments are summarized below.

Population

Boserup's (1965) theory of population growth as the primary cause for agricultural intensification found much support among anthropologists and archaeologists. Such a pattern was documented among modern-day farmers in Africa and the Americas, and the definition was further refined (e.g., Brookfield 1984; Turner et al. 1993). Archaeologists argued that there was support for population causing agricultural intensification in areas such as Peru (Cohen 1977).

Boserup's theory has also received much critique. One set of critiques focuses on Boserup's unilinear evolutionary scheme of ever-decreasing fallow periods as the primary trajectory of intensification (Table 1). As described in the section on agricultural practices above, however, there are many ways to increase production such as

Agricultural Practice: Transformation Through Time, Table 1 Esther Boserup's (1965: 15–16) intensification scheme of decreasing fallow periods

Types of land use	Fallow period	Vegetation
Forest-fallow cultivation	>10 years	Forest regeneration
Bush-fallow cultivation	5–10 years	Some shrub, tree regeneration
Short-fallow cultivation	1–2 years	Grass regeneration
Annual cropping	Months	Cropped once a year
Mutli-cropping	None	Cropped two or more times a year

implementing innovative irrigation or cropping systems (Morrison 1994). Another critique focuses on her lack of consideration for the role of environmental or ecological variables. She saw the evolution of ever-decreasing fallow as independent of local environmental conditions, but new research shows this may not be the case. Finally, researchers have found other reasons as to why people may intensify agriculture aside from population growth. These ideas are discussed in more detail below.

Environmental Conditions

Boserup challenged environmentally deterministic models but to such an extent that she largely ignored how natural conditions shape the dynamics of agricultural systems. Boserup's scheme of forest fallow to multi-cropping is not applicable to more arid regions. As Wittfogel (1956) and Steward (1955) pointed out early on, the primary means of intensification in particularly arid regions is through irrigation.

In some cases, environmental conditions prohibit the possibility of intensification. In extremely arid regions, where rainfall is highly variable (seasonally and/or annually) and where irrigation is not possible, it is not worth increasing investment in fields that will likely fail due to drought. This seems to have been the case in the Wupatki region of New Mexico in the twelfth century CE (Stone and Downum 1999). Here, a volcanic eruption deposited fertile ash in a valley normally not suitable for agricultural production. Although the population did subsequently increase in the area, rather than intensify the production of individual fields, settlement patterns and territory markers indicate that farmers protected large areas of land in order to maintain a more extensive land-use strategy because intensification would have been too risky in this particularly arid region.

Finally, researchers argue that in some regions where rainfall is unpredictable, intensification practices, such as terracing or irrigation, are not implemented to meet the needs of population pressure but as a risk reduction strategy. For example, maize irrigation in parts of the Basin of Mexico did not increase yields compared to successful dryland farming but secured the production of the crop during years of low rainfall (Nichols 1987).

Social and Political Variables

Another important topic related to explaining agricultural transformations is the role of social and political variables. One theory is that agriculture is often intensified to meet political rather than population demands. For example, in New Guinea and the Pacific Islands, communities overproduce pigs and taro or yams for large feasts that will boost the social status of certain individuals. Although one result is the increased power and prestige of particular individuals, the community members also benefit by taking part in the feasts and ceremonies sponsored by this individual (Brookfield 1972). Shifts in political power can also drastically transform how and what types of food are produced. Expansive states and empires often reorganized food production in their new territories. For example, the Inca empire shifted highland potato farmers into lowland valleys and required them to produce more maize (Hastorf 1993).

The other issue that links social and political power to agricultural transformations is the "hydraulic hypothesis" proposed by Steward (1955) and Wittfogel (1956). They posited that complex irrigation or field systems require a more centralized form of governance. Much

like Boserup's intensification model, Steward and Wittfogel's ideas generated much enthusiasm. Archaeologists argued that the irrigated pondfield systems of the Hawaiian Islands were governed by complex chiefdoms (Earle 1980) and that the large-scale raised-field production in the Lake Titicaca Basin of Bolivia was directed by the Tiwanaku state (Kolata 1986). This model has been challenged, however, with ethnographic and archaeological cases showing how decentralized communities can operate large-scale irrigation and field systems such as on the north coast of Peru (Netherly 1984).

The theories summarized above focus primarily on single causes such as population, environment, or politics that bring about changes in an agricultural system. As archaeologists have learned more about the complexities of past and present agricultural systems, they have realized that no single factor or "prime mover" can explain how they developed and changed (Morrison 1996). For this reason, archaeologists now aim to understand the multivariable processes or courses of agricultural change by considering multiple archaeological datasets, such as those described above.

International Perspectives

From the examples provided above, the study of past agricultural strategies and transformations has been quite international and comparative in nature. Aside from teaching us about past dynamics in agricultural systems, archaeological studies of agricultural transformation have the potential to inform us about modern-day agricultural issues.

Rehabilitation of Ancient Farming Technologies

In some underdeveloped countries and regions, the study of lost, ancient agricultural techniques has led to rehabilitation projects aimed at improving local economies. For example, there have been several raised-field rehabilitation projects in highland and lowland Bolivia and Peru (Fig. 2). Ancient raised fields that were likely in use between 800 and 1200 CE were reconstructed in the Lake Titicaca basin of the Andean highlands (Erickson 1988; Kolata and Ortloff 1996), and the Llanos de Moxos of the Amazon basin (Erickson 1980). Initial experiments showed them to be highly productive. Several development projects aimed at helping these communities use this technology to improve food production were

Agricultural Practice: Transformation Through Time, Fig. 2 Ancient raised fields in the Pampa Koani, Bolivia

instituted but none of them lasted very long (Swartely 2002). Why these projects were unsuccessful has forced archaeologists to think more carefully about the differences in food production between today and the past and about our models of how these field systems originally functioned. Were raised fields used because they were more productive than dryland fields, or did they simply supplement dryland agriculture? Is the labor and effort needed to construct and maintain such field systems too great for small communities? Or has the economic structure of the modern, market and city-oriented labor force made rural, agricultural projects that require large, continuous labor inputs no longer viable or valuable? While such projects have the potential to help modern-day communities, they also help us refine our understanding of the past.

Future Directions

Archaeologists continue to pursue more information on the particular trajectories of agricultural transformation across the globe. The trend towards considering a broader range of reasons for and strategies of agricultural change will lead us to a better understanding of both differences and similarities among different world regions. Early studies of agricultural change tended to focus on landscape modifications such as field and irrigation systems. While we will continue to learn more about such systems with new technologies such as LiDAR, the greatest advancements will be made through analytical techniques in botanical and geochemical analyses that reflect other important agricultural practices such as fertilization, soil management, and pest control.

Agricultural Practices: A Case Study from Papua New Guinea

Tim Denham
Archaeological Science Programs, School of Archaeology and Anthropology, ANU College of Arts and Social Sciences, The Australian National University, Canberra, ACT, Australia

Introduction and Definition

A useful methodological tool to help unravel the complexities of how early agriculture emerged within a given locale is the concept of "practice" (following Bourdieu 1990; see Denham 2005, 2009, 2011; Denham and Haberle 2008; Bruno 2009; Jussuret 2010). In archaeology, practices represent human actions in the past, including habitual modes of behavior and dispositions, as well as individual idiosyncrasies (Barrett 1994). As such, the concept of practice has been proposed as a useful way to overcome various dualisms, or binary divisions, that permeate the study of human-environment interactions and social relations, whether in the past or present (Fig. 1; Denham and Haberle 2008; Denham 2009).

From one perspective, practices represent the nexus of human-environment relations because they mark the intersection of social life with the biosphere and geosphere (Fig. 1a); practices are

Agricultural Practices: A Case Study from Papua New Guinea, Fig. 1 Schematic diagram showing how the concept of practice reconciles various dichotomies inherent to the understanding of human-environment (*upper*) and human-human (social) relations (*lower*) in the past. (Amended version of Denham and Haberle 2008: Fig. 2)

structured by the environment, while simultaneously acting upon and changing that environment. Any practice represents the intersection between people and their world. From another perspective, practices are a manifestation of, and represent the nexus of, more abstract structure-agency dichotomies that pervade the social sciences and humanities (Fig. 1b). Practices focus upon what people did rather than upon seeking to unravel the degrees to which someone's actions are structurally determined (whether by social, economic, or mental structures) or represent their predispositions or are a product of individual improvisation. As such, practices subsume and encapsulate the inherent recursivity of human-environment interactions and social relations, respectively.

The concept of practice, though, does not address questions of ultimate causation, which remain open to variable speculation (Denham and Haberle 2008: 484–485):

> . . . in trying to explain why people did something in the past – whether in terms of what caused something to happen or in terms of what it meant to people in the past – we are continually drawing on our own frames of reference about how people behave and what governs that behaviour, ie, we continually fall back on patterns of thinking derived from our understanding of the world today. Consequently, we populate the past with *Homo economicus* and *H. ecologicus*, such as resource maximisers and optimal foragers . . ., or we try to distinguish conscious or unconscious patterns of behaviour from the evidence of past practices. . .. In attempting to address questions of 'why?' there is a continual interplay between what happened in the past and how that past is made meaningful in the present.

Having said this, a focus on practice draws our attention away from questions of "why," or from questions of ultimate causality, to the "what" and "how" something happened in the past. As a result, the concept has considerable utility for understanding the emergence of agriculture in a particular locale.

Key Issues

A Practice-Centered Method for Investigating Early Agriculture

A practice-centered approach is useful for archaeologists studying early agriculture because it focuses attention upon the multidisciplinary evidence of what people did in the past. Specific practices associated with cultivation may potentially include burning, forest clearance, gathering, plot preparation, transplantation, planting of seed, dibbling, staking of plants, tillage, construction of raised beds and mounds, and digging of drains or ditches. Some of these are relatively generic, constituent practices that are common to many forms of plant exploitation, including agriculture. As such, a practice-based framework provides common conceptual ground to understand and compare different forms of plant exploitation, such as agriculture and foraging, and to chart how these were transformed through time and across space (Denham 2008; Denham et al. 2009).

Within this conceptual framework, forms of plant exploitation represent higher-order categories associated with how various constituent practices co-occur, or are "bundled," within particular historico-geographical contexts. This bundling effectively reconstructs how constituent practices articulate and intersect within a locale at different times in order to determine which forms of plant exploitation plausibly occurred in the past and to show how these were transformed through time (following Hägerstrand 1970). This practice-centered method is designed to circumvent some of the laden "semantic" (Harris 1996) debates concerning the definition and attribution of monolithic categories such as "agriculture" or "foraging" to different forms of plant exploitation in the past.

Methodologically, a chronology of practices in the past can be reconstructed relatively directly from archaeological remains and indirectly through the interpretation of paleoenvironmental proxies, such as charcoal, phytoliths, pollen, and sediments. Using the Kuk Swamp evidence from the highlands of Papua New Guinea as an example, archaeological evidence of past plant exploitation and cultivation practices has grounded more equivocal paleoecological evidence of landscape transformation and archaeobotanical evidence for the presence and use of food plants (Denham and Haberle 2008). It is not just that multidisciplinary evidence for different practices co-occurs in time and place, but the archaeological evidence enables the different lines of evidence to be integrated and linked to specific practices, thereby enabling their "bundling" into forms of plant exploitation.

At Kuk Swamp, archaeological excavations documented artificially constructed mounds dating to 7000–6400 cal BP on the wetland margin. One of the fills between these mounds contained anomalously high *Musa* spp. banana phytoliths, while paleoecological evidence from several fills indicated a dramatic transformation of the landscape to grassland at this time (Denham et al. 2003). In the highland New Guinea context, these lines of evidence suggest mounded cultivation of crops, including bananas, as well as the exploitation of tuberous plants on the wetland margin within a landscape denuded and maintained as grassland.

The multidisciplinary evidence, the chronology of practices, and the interpretation of plant exploitation in the past should be reconstructed for a particular landscape or restricted region, rather on broader spatial (or chronological) scales. Today cultivation practices and major crop plants can vary considerably across Papua New Guinea, including from one valley to another (Bourke and Harwood 2009). Similarly, forms of plant exploitation are likely to have varied considerably across the island of New Guinea in the distant past (Denham 2005, 2011). In seeking to reconstruct plant exploitation in the distant past, particularly the emergence of agriculture, the conflation of records from geographically dispersed regions may provide a highly inaccurate portrayal of what actually happened at any given locale – the interpretative sum can be greater than the evidential parts (Denham 2009: 661).

These ideas are illustrated, and have been developed in order to understand, the long-term history of plant exploitation and the emergence and transformation of agriculture in the highlands of New Guinea.

Agricultural Practices: A Case Study from Papua New Guinea, Fig. 2 Chronology of practices and associated forms of plant exploitation reconstructed for the Upper Wahgi Valley using multidisciplinary lines of evidence. (Amended version of Denham and Haberle 2008: Fig. 9)

Early Agriculture in the Upper Wahgi Valley, Papua New Guinea

Various lines of multidisciplinary evidence have been used to reconstruct a chronology of practices in the past for the Upper Wahgi Valley, Papua New Guinea (Fig. 2; following Denham and Haberle 2008). The chronology of practices has been cross-referenced with, and bundled into, forms of plant exploitation that have been documented ethnographically in the region. The chronology and resultant interpretations are secure because they are derived from archaeological, geomorphological, and paleoecological investigations at multiple sites (including wetlands, rockshelters, and open sites) within a confined region of one valley in the highlands.

The practice-centered method charts the emergence and transformation of agriculture through time in the Upper Wahgi Valley (Fig. 3). Continuities with earlier forms of plant exploitation, such as from foraging to shifting cultivation, are clearly demonstrated. To illustrate, multiple constituent practices are associated with traditional forms of foraging that occurred since the beginning of the Holocene, including burning, forest disturbance, tree exploitation, tuber exploitation, and digging. The additions of plot preparation, staking, and inferential evidence for planting to the practical repertoire are suggestive of some form of shifting cultivation on the floor of the Upper Wahgi Valley during the early Holocene. Additional definitive evidence for planting and mound construction indicates more intensive forms of cultivation on the wetland margin at Kuk Swamp at 7000–6400 cal BP. Subsequent innovations, introductions, and transformations of agriculture occurred following the inception of ditch digging from 4400 to 4000 years ago, the adoption of *Casuarina* tree fallowing from c. 1200 years ago, and intensive pig rearing and sweet potato cultivation within the last few hundred years.

Each transformation, or augmentation of the plant exploitation repertoire, results from the adoption of additional practices, whether of local innovation or extralocal introduction. Significantly, forms of plant exploitation need not be supplanted by successive transformations. In the Upper Wahgi Valley context, each reconstructed

Agricultural Practices: A Case Study from Papua New Guinea, Fig. 3 Schematic representation of the bundling of practices into forms of plant exploitation reconstructed for the Upper Wahgi Valley during the early-to-mid Holocene. (Amended version of Denham 2009: Fig. 2)

form of plant exploitation broadens the repertoire that people draw upon simultaneously in different parts of the landscape. Consequently, the long-term history of agriculture is not unilinear; rather it becomes increasingly multilinear and adaptive to different parts of the landscape, as well as to

different landscapes, through time. The practice-centered method is designed to highlight the transformative aspects of plant exploitation, rather than viewing each form as a static, monolithic entity (Denham 2009).

Agriculture: Definition and Overview

David R. Harris and Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

State of Knowledge and Current Debates

Introduction

Agriculture is the most comprehensive word used to denote the many ways in which crop plants and domestic animals sustain the global human population by providing food and other products. The English word agriculture derives from the Latin *ager* (field) and *colo* (cultivate) signifying, when combined, the Latin *agricultura*: field or land tillage. But the word has come to subsume a very wide spectrum of activities that are integral to agriculture and have their own descriptive terms, such as cultivation, domestication, horticulture, arboriculture, and vegeculture, as well as forms of livestock management such as mixed crop-livestock farming, pastoralism, and transhumance. Also agriculture is frequently qualified by words such as incipient, proto, shifting, extensive, and intensive, the precise meaning of which is not self-evident. Many different attributes are used too to define particular forms of agriculture, such as soil type, frequency of cultivation, and principal crops or animals. The term agriculture is occasionally restricted to crop cultivation excluding the raising of domestic animals, although it

usually implies both activities. The Oxford English Dictionary (1971) defines agriculture very broadly as "The science and art of cultivating the soil, including the allied pursuits of gathering in the crops and rearing live stock (*sic*); tillage, husbandry, farming (in the widest sense)." In this entry, we too use the term in its broadest, inclusive sense.

In the published literature on early agriculture, there is a tendency for the word agriculture and many of its subsidiary terms to be used vaguely without precise definition, and sometimes their connotations overlap, for example, proto/incipient and shifting/extensive. There is need to clarify much agricultural terminology to avoid confusion (Harris 2007: 17–26), particularly because the multidisciplinary nature of research on the subject leads to many concepts being used that derive from disparate disciplines; principally archaeology, anthropology, biogeography, genetics, linguistics, and taxonomy. In this entry, we cannot review comprehensively all the typological terms currently used in discussions of the origins and early development of agriculture. Instead we focus on the two most fundamental processes that led to agriculture, cultivation and domestication (of plants and animals), and then comment on some of the terms used to denote particular categories of agricultural production. In conclusion, we return to agriculture itself as a process of landscape-scale food production.

This approach, leading from consideration of cultivation through domestication to agriculture (Fig. 1), proposes that agriculture is a form of land use and economy that resulted from the combination of cultivation (a bundle of human actions focused on preparing soil and planting, tending, and harvesting plants) and domestication (a bundle of genetic and morphological changes that have increased the ability of plants to adapt to cultivation). Cultivation and domestication are related as cause and effect, a change in human strategy with consequences in genetic adaptations of another organism, which increased the interdependencies of both. In the next two sections, we explore the nature of and interaction between cultivation and domestication over time in light of mainly archaeological evidence together with some genetic data, including exploration of the concept of "pre-domestication cultivation."

Agriculture: Definition and Overview, Fig. 1 An evolutionary model from foraging to agriculture, in which the transitions to cultivation, domestication, and agriculture are separated and potential archaeological indicators are suggested (Modified from Harris 1989 and Fuller 2007)

Cultivation

Cultivation is an activity through which humans become directly involved in the management of the lives and life cycles of certain plants. In abstract terms, this can be considered a change from a largely extractive approach to subsistence (collecting) towards a highly regulative one (Ellen 1994), with seasonal scheduling of labor for delayed returns and storable product. In practice, cultivation involves manipulation of soil, water, and other components of the plant environment. At its most basic, it involves sowing of seeds on soil which has been cleared of other vegetation. In low-intensity systems, this may come about through burning of vegetation (slash and burn) or by taking advantage of fresh deposits of silt by river floods (e.g., *décrue* agriculture; Harlan and Pasquereau 1969). It usually involves preparation of the soil by tillage. Tillage methods and tools vary from simple handheld devices (digging sticks, spades, hoes) to team-employed tools, such as the Andean "foot-plough," to animal-powered ards and true ploughs (Steensburg 1986). Other important variables include the addition of nutrients to the soil by such means as manuring, multiple cropping with nitrogen-fixing species (usually legumes of the family Fabaceae), or using crop rotations with legumes or fallow periods. This represents an important component of cultivation, i.e., scheduling the seasons of sowing and harvesting and interannual patterns in crop rotation and fallowing.

Water is a key input into any cultivation system, and in some regions it had a central role in the origins of agriculture. For example, control of water levels was essential in the development of early rice cultivation in China (Fuller and Qin 2009). Successful cultivation of the perennial ancestor of *japonica* rice involved extending shallow and wetland-margin habitats by clearing competing vegetation, as use of these slightly less-watered microenvironments would have increased grain production. The earliest preserved field systems for rice cultivation consist of small (1–2 m diameter) fields interconnected to each other and to frequent deep water pits that served to drain water from the growing rice.

Cultivation represents an important change in human strategy as people start to manipulate the soil and the composition of plant communities to enhance yields of particular plants later. This has led many researchers to infer that morphological domestication came about through unconscious selection. In other words, people did not set out to domesticate plants but to manipulate productivity through cultivation. The new environment created by cultivation can cause unintended domestication, as the cultivated species adapts to these new circumstances.

In recent years, archaeobotanical research has aimed to identify the practices of cultivation prior to the emergence of domesticated species. Such evidence for pre-domestication cultivation can be inferred from the presence of arable weed assemblages, which may be demonstrated by the statistical composition of wild-seed assemblages or by the modern ecological characteristics of species that recur archaeologically but have little or no known human uses (Willcox 2012). As is well known from later agricultural periods, archaeobotanical assemblages are made up predominately of crops and weeds, together with some gathered fruits and nuts, and this pattern begins to emerge by the earliest Pre-Pottery Neolithic in Southwest Asia and in the middle Neolithic in parts of China (Fuller and Qin 2010). This approach draws on the well-developed tradition in European archaeobotany of using weed-seed assemblages to infer the cultivation ecology of fields (Jones 1988).

Domestication

Domestication is most clearly defined as a biological phenomenon, that is, by traits in crops that result from adaptation to cultivation and by which they differ from close wild relatives. Several recurrent "domestication syndromes" can be recognized as sets of characters that define domesticated crops and characterize domestication as a form of convergent evolution under cultivation (Fuller 2007). The domestication syndrome differs for different kinds of crop plants, according primarily to how they are reproduced, by seed or by cuttings, and what plant organ is the target of selection (grain, fruit, tuber).

The best defined domestication syndrome is that for grain crops, including cereals, pulses, and oilseeds. While all of these traits are the product of cycles of harvesting and sowing from such harvests, the actual selection pressures seem to come from two different aspects of cultivation. First are some traits selected for by harvesting and the crops' growing reliance on humans for seed dispersal. Second are traits that relate to soil conditions, as tilled fields are essentially early successional communities on empty soil, which is generally loose and allows deeper burial of seeds. Although there are six essential syndrome traits in seed crops, only the first four have some chance of archaeobotanical preservation in some species.

First (1) is the elimination of natural seed dispersal, such as through non-shattering rachis in cereals and non-dehiscent pod in pulses and oilseeds. This is often regarded as the single most important domestication trait as it makes a species dependent upon the farmer for survival. It also means that human labor must be used to thresh crops and separate seeds, pods, or spikelets instead of natural dispersal occurring at maturity (Fuller et al. 2010). This trait can only evolve under conditions of harvesting, such as uprooting, use of sickles, or harvesting when crops are mature rather than green. This trait is readily identifiable in cereal rachis or spikelet-base remains, and has been studied in rice, wheats, barley, pearl millet, and maize, but is less evident in the preserved remains of many other crops. However, not all harvesting methods necessarily select for this, which means there are conceivable systems of "non-domestication cultivation" (Hillman and Davies 1990), or there may be weak selection leading to very protracted evolution of this trait within populations (Fuller 2007; Allaby 2010). It is worth noting that any individual plant, or archaeological specimen, either has wild-type or domesticated-type dispersal, but domestication is working on populations, and therefore domestication status should be determined for assemblages as representative of past populations. Recent archaeobotanical evidence tends to suggest relatively weak selection for this trait (Fuller et al. 2010).

A second connected trait (2) is reduction in aids to wild seed dispersal. Plants often have a range of structures that aid seed dispersal, including hairs, barbs, awns, and even the general shape of the spikelet in grasses. Thus domesticated wheat spikelets are less hairy, have shorter or no awns, and are plump, whereas in the wild they are heavily haired, barbed, and aerodynamic in shape. Varieties of wild rice are always awned and heavily barbed, while many cultivars are awnless and those with awns have fewer barbs. Rather than being positively selected by harvesting, this comes about by removal of natural selection for wild-type dispersal adaptations, and therefore under domestication, such traits require less metabolic expenditure. This trait may sometimes be visible in archaeobotanical material but is rare and non-diagnostic and does not provide a definitive means of identifying domestication archaeologically. Because this trait shifts gradually and non-diagnostically, it can be regarded as indicating "semidomestication."

Two additional traits of the domestication syndrome may be widespread, but they are not recoverable archaeologically: (3) synchronous tillering and ripening, sometimes including a shift from perennial to annual. Planting at one time and harvesting at one time will favor plants that grow in synchronization. Another trait (4) is a more compact growth habit with apical dominance, such as a reduction in side branching and denser spikes or seed heads. In some species, such as in several pulses, this involved a shift from a climbing habit to self-standing. Harvesting methods, like those that select for non-shattering types, can also favor plants with single and compact parts to be harvested.

Two more important traits are thought to relate primarily to an aspect of soil conditions, i.e., planting seeds into more deeply tilled soils. These are traits that relate to rapid germination and early growth. On the one hand (5) is the loss of germination inhibition. In the wild, many seeds will only germinate after certain conditions have passed – conditions of day length and temperature – or after the seed coat is physically damaged. In wild legumes, for example, this may mean that 90% of seeds will fail to germinate. By contrast,

crops tend to germinate as soon as they are wet and planted. This is simply selected by planting as those seeds that do not germinate will fail to contribute to the next harvest and subsequent crops planted from it. This is regarded as a key domestication trait, especially in pulses and pseudo-cereals (e.g., *Chenopodium* spp.) This change is often signalled by changes in the seed, such as thinner and less ornamented seed coats. On the other hand it is a trait, widely studied in archaeobotany, that can be regarded as a "semidomestication" trait. Trait 6 is increasing seed/fruit size. This is likely to be selected for by open environments and deep burial in disturbed soils. This has the added advantage of increased seed weight which tends to increase harvest yields from a given number of crop plants. Comparative studies, for example, between related species, show that larger seeds germinate more quickly and effectively than smaller seeds, and thus this should be selected for by tillage and cultivation generally. As seeds readily preserve, archaeological populations of them can be measured to track changes in average sizes and size ranges, to trace this trait over time. In the case of cereals, selection seems to be focused on seed thickness/breadth rather than length (Fuller et al. 2010).

While for seed crops, predominance of the above traits marks domestication, the end of a process of biological evolution, the determination of domestication sequences is much more difficult in vegetatively cultivated plants such as roots and tubers (Hildebrand 2003, and see the section below on Vegeculture). Because harvest of tubers focuses on a starchy storage organ rather than a reproductive organ, harvesting practices by humans are unlikely to pose strong selective pressures on the next generation. In addition, because tuber plants tend to be perennials, the harvested individual will tend to grow back, reducing the potential to select for improvements across generations. In many cases, cultivation practices may induce the useful part of the plant – the starchy organ – to exhibit phenotypic alteration without changes in its genotypic makeup, such as the improved tuber size produced by yams in loosened, prepared soil as opposed to harder unprepared soils (Chikwendu and Okezie 1989). Thus tuber crops can be cultivated for long periods and on an extensive field scale without undergoing morphological domestication. In addition, archaeologically recovered tuber fragments (parenchyma) tend to preserve few morphological attributes relevant to phenotypic or genotypic change. There is some research which suggests that micro-remains such as starch grains have increased in size with tuber domestication (Piperno 2012). As a result of these factors, the study of early vegecultural systems tends to focus on establishing the presence of potential crop species and inferring practices of landscape modification and management, such as soil mounding, ditch digging, and vegetation burning (see, e.g., Denham 2007).

Specialized Types of Livestock Management and Crop Production

In this section, we examine briefly several distinctive types of agriculture that developed over time into specialized systems focused on the production of food and often also secondary products such as hides, hair, wool, building materials, and many other useful items.

Mixed Crop-Livestock Farming

One of the most significant variables in the historical differentiation of agricultural systems is whether domestic livestock were fully integrated with the processes of crop cultivation as beasts of burden and agents of soil fertilization as well as producers of food. Such systems of "mixed farming" or "agropastoralism" developed early in only a few regions. They did so most comprehensively in Southwest Asia (and later in Europe) where domesticated herd animals – cattle, sheep, goats, and pigs – were raised in close conjunction with wheat, barley, and other cereal and pulse crops as producers of meat, milk, hides, hair, wool, and dung and as traction animals used for ploughing, load-bearing, and other purposes (Harris 2002). A comparable system of mixed farming evolved in East and Southeast Asia where water buffaloes became an integral component of the system of wet-rice (padi) cultivation (Hoffpauir 2000), although this may have been millennia after rice had spread

throughout China and much of Southeast Asia (Fuller et al. 2011).

In other regions of early agriculture where domestic herd animals were present, they were not fully integrated with crop cultivation as providers of food, fertilizer, and traction. Thus, in northern tropical Africa, cattle, camels, sheep, and goats, and in the Andean region of South America camelids (llama and alpaca), were not fully incorporated into indigenous systems of cereal, pulse, and root-crop cultivation.

Pastoralism

The full incorporation of domestic herd animals into systems of mixed farming requires permanent facilities such as barns, sheds, stalls, fenced fields, and other enclosures for confining the animals and controlling their movements. This contrasts with pastoral systems that are characterized by more mobile methods of management. The term pastoralism derives from the Latin *pastor*, meaning a herdsman or shepherd, and it applies to mobile systems in which the herd animals, principally sheep, goats, cattle, horses, donkeys, camels, llamas, alpacas, and reindeer, are raised to provide food and other products and as pack and riding animals. The essence of pastoralism is that people move with their animals. The spatial and temporal scales of their movements range from short daily movements of flocks and herds to and from pastures near their owners' settlements (diurnal grazing) to longer seasonal movements by part of the local community with their animals to higher and/or more distant pastures (transhumance), to the most fully mobile system in which families migrate from pasture to pasture with their herds throughout the year and from year to year (nomadic pastoralism). Nomadic pastoralists own and largely depend on their animals, although they have historically obtained some of their food and other supplies by trading with or raiding settled agricultural communities. In fact, all nomadic pastoralists depend to some degree on crop products for their food and often also for supplementary fodder for their animals.

Few if any fully nomadic pastoral groups still exist in the modern world, but in the historical and prehistoric past, this way of life was followed extensively in the deserts of northern and eastern Africa and southwestern and central Asia. The pastoralists' herds consisted mainly of sheep and goats, with the roles of horses and camels varying from region to region, and in the high latitudes of Eurasia a variant form of reindeer pastoralism became established (Ingold 1980).

Horticulture

Horticulture has two contrasted connotations in the literature on traditional agricultural systems and the origins of agriculture. The first relates directly to the origin of the word from the Latin *hortus*, meaning garden (juxtaposed to *ager*, field), and in this literal sense it refers to the cultivation of plots of land adjacent or quite close to the houses of the cultivators. Such gardens are normally smaller than fields, which are usually located farther from their associated settlements. A greater variety of plants, especially perennial shrubs and trees, tend to be cultivated in gardens than in fields, which are commonly devoted to one or only a few types of crop. Also, whereas most fields are cultivated in seasonal cycles, gardens are usually tended continuously, especially in the tropics where long growing periods favor year-round production. Another distinctive feature of house gardens is the presence in them of many adventitious wild and weedy plants. They add to the floristic and structural diversity of the plant community and enhance its ability to provide a great variety of edible, medicinal, and other products such as flowers, fibers, dyes, containers, and construction materials (see, e.g., Coomes and Ban 2004).

The contrasts in size and floristic diversity between gardens and fields are widely recognized in the literature on early agriculture, for example, in the terms "fixed-plot horticulture" and shifting or "swidden" cultivation and the German *gartenbau* and *ackerbau*. Small, continuously tended plots close to dwellings have been proposed as probable arenas of early plant domestication (Harris 1973: 398–401), but very little archaeobotanical research on past garden cultivation has as yet been undertaken.

Secondly, the terms horticulture and gardening have been used to denote agricultural systems that

combine field cultivation of annual root and/or seed crops with growing mainly perennial tree, shrub, and herbaceous plants in gardens – a mixed cropping system that, when trees are a major component, is sometimes alternatively described as agroforestry. This connotation of horticulture has been used particularly in descriptions of traditional, and by implication early, systems of cultivation in Melanesia and the Pacific Islands, but this usage tends to obscure the useful distinction between field and garden cultivation.

Arboriculture

The term arboriculture, from *arbor* the Latin for tree, is used to specify agricultural systems focused exclusively or largely on the cultivation of trees and shrubs for the production of fruits and seeds and, in some species, also for ancillary products such as wood for construction and leaves for thatch, fiber, etc. The term, which is sometimes equated with agroforestry (see above), refers mainly to the specialized cultivation of fruit- and nut-bearing trees and shrubs in single- or mixed-species orchards and plantations. It can refer also to plantations of trees for timber production, although this process is more usually described as forestry.

Arboriculture differs from horticulture in that the plants are grown in less floristically diverse communities on larger landholdings. Traditional systems of arboriculture include oil-palm plantations in tropical West Africa and olive, almond, and walnut orchards in the circum-Mediterranean region. Arboriculture has attracted much less attention in the literature on the beginnings and early development of agriculture than the cultivation of cereal, pulse, and root crops, and fruit- and nut-bearing trees are likely to have been a much more important source of food among many hunter-gatherer groups than among early farmers (Harris 2012: 37–9). It tends to be difficult to differentiate specialized arboriculture from more floristically mixed traditional systems of horticulture, and it is seldom possible to do so on the basis of archaeobotanical data alone (see, e.g., Gosden 1995 and Latinis 2000). At present, most of what can be inferred about arboriculture in premodern times comes from historical and ethnoecological evidence.

Vegeculture

The word vegeculture is used to describe agricultural systems that produce mainly root and tuber crops with underground storage organs consisting of starch-rich roots, root and stem tubers, corms, and rhizomes. The crops are reproduced asexually by planting pieces of a parent plant such as parts of tubers, stem cuttings, or sprouts, rather than being grown from seed. Vegetative reproduction made possible the domestication of tuberous plants by replicating the characteristics of parent clones and then selecting and multiplying useful phenotypic variations that arose in planted stock, such as unusually large or smooth-skinned tubers. The process did not involve directional genotypic change from wild progenitor to domesticate as occurred in seed-crop domestication. Root and tuber domestication has taken place within the limits of phenotypic variation determined by an unaltered genotype, but morphological changes under domestication have nevertheless been substantial, for example, decreased flowering and in tubers changes towards greater size and starch content and reduction in bitterness and in the numbers and length of thorns.

Although root and tuber and seed crops are often cultivated together, vegeculture is the traditional mode of agricultural production in many parts of the humid and seasonally dry tropics. Until recently, little macrobotanical evidence of vegeculture had been found because the soft tissues of root and tuber crops are seldom preserved (except in very dry or waterlogged archaeological contexts), but advances in microbotanical techniques for identifying remains of tuberous plants in the form of phytoliths (silicified particles of plant tissues), parenchyma (vegetative storage plant tissues), and starch grains preserved in sedimentary deposits are now beginning to illuminate the prehistory of vegeculture in several regions of the tropics (Hather 1994; Fullager et al. 2006; Piperno 2012).

Agriculture as Landscapes of Food Production

The beginnings of food production represent a strategic shift in human behavior, towards the manipulation of the soil environment and through an influence on the composition of plant populations grown in that soil, via preferential seeding and tending of one or a few species. While cultivation may involve a range of practices, and these will tend to select for morphological domestication, at least in seed crops, we can define agriculture in relation to the scale of cultivation, its prominence in local landscapes and in contributing a major component of human diet. In this sense, *agriculture* is the form of land use that represents a *change in the landscape*, as people regularly cultivate, raise, and focus more attention on domestic plants and/or animals. Agriculture creates fields for larger-scale production of crops and livestock. While small-scale cultivation may involve a few plants, agriculture involves the creation of substantial fields of sown vegetation on such a scale that it should, in principle, be recognizable in regional palaeovegetation datasets, recoverable from palaeosols, and a prominent part of the inferred source of archaeological plant remains. How one distinguishes agriculture from small-scale cultivation varies according to the parameters of particular geographical and cultural contexts.

Irrigation systems are one notable and widespread way in which distinctive landscapes of agriculture have been created. Control of water can be focused either on its removal (drainage) or by adding water to otherwise locally dry areas to allow cultivation where rainfall is insufficient to enhance productivity. In riverine agriculture, such as that associated with ancient Mesopotamia and Egypt (Butzer 1976), this took the form of canals and basins that helped to conserve floodwater and distribute it more evenly and widely. In some mountain environments, such as the Andes, canal systems, often closely associated with cultivated terraces, were also developed to bring steep slopes into agricultural production (Donkin 1979). Some irrigation systems incorporated manual water-lifting devices, such as the *shaduf* which was widespread in Egypt and Southwest Asia by c. 1500 BCE and allowed buckets of water to be raised above the level of canals and fed onto the fields. By the Classical era, cattle-driven water wheels (*saqia*) made lifting water more efficient and increased the extent of arable lands in river valleys. In regions that relied on rainfall for cultivation, deep wells to tap into groundwater, and surface reservoirs (tanks), were developed to store water. In some of the driest margins of cultivation around the Iranian plateau, in Central Asia, Arabia, and the Sahara, systems of underground tunnels or galleries (*qanats*, *karez*, *foggara*) began to be built several thousand years ago to collect subsurface water from piedmont slopes and direct it out to fields and palm groves in the adjacent plains (see, e.g., English 1968; Magee 2005).

Many other types of agricultural landscape, not referred to here, were developed in premodern times as an increasing proportion of the inhabited earth's surface was transformed by agriculture and as the human population became progressively more dependent through the Holocene, for its food and other needs, on a growing number of domesticated plant and animal species.

Agroforestry: Environmental Archaeological Approaches

Jean Kennedy
Archaeology and Natural History, School of Culture, History and Language, College of Asia and the Pacific, Australian National University, Canberra, ACT, Australia

Introduction

Agroforestry, the deliberate incorporation of trees in farming systems, is a very widespread practice with many variants, some of them presumably ancient. Archaeological investigation of these systems requires multidisciplinary research across disparate temporal and spatial scales, combining archaeobotanical, paleoecological, and ethnobotanical studies and focusing on agroecosystems rather than their individual constituents. The recent increase in such studies is part of a growing awareness of the intricacies of past human impacts on environments and of the diverse and complex histories of farming. Recognition of the biodiversity and variability of management practices in traditional agricultural systems has begun to stimulate revised models of the trajectories of peopled landscapes. New research questions in archaeology are supported by an expanding array of analytical techniques which draw on a wide range of sciences including molecular biology, genetics, chemistry, geophysics, information technology, and ecology.

The characteristics of trees, especially their slow maturation and long life, contrast with those of the annual and short-lived crops most often emphasized in archaeological studies of the origins and development of agriculture. Understanding the incorporation of trees in agroecosystems requires research at scales encompassing whole landscapes and long sequences of environmental change at fine resolution. Revised models of the effects of human manipulations of plant communities are developing as archaeobotanical, paleoecological, and associated research gradually expands the information base.

Definition

The Oxford English Dictionary lists "agroforestry (n.d.) as agriculture in which there is integrated management of trees or shrubs along with conventional crops or livestock" (http://www.oed.com/view/Entry/4197 [accessed June 26, 2012]) and cites the following earliest usage from Bene et al. (1977: 41): "One of the objectives of ∗agroforestry is to 'domesticate' and upgrade shifting agriculture to maximize sustained production on less well-endowed land."

Definitions of agroforestry that state similar objectives, and prescribe remediation of damage caused by unsound agricultural practices, are common in literature on rural development. Usage of the term agroforestry has extended to include many forms of polycultural farming in which trees are incorporated, practiced by independent small-scale farmers worldwide. In this broader usage, agroforestry may be synonymous with or include arboriculture, forest farming, orchard-gardens, silviculture, and similar terms. Clarke and Thaman (1993) distinguished the first, prescriptive definitions as constituting institutional agroforestry and the second broader usage as traditional or indigenous agroforestry. In the second sense, agroforestry is a useful collective

name for land-use systems in which woody perennials are deliberately grown on the same piece of land as agricultural crops and/or animals, either in some form of spatial arrangement or in sequence.

Historical Background

The word agroforestry came into common use with the establishment of the International Council for Research in Agroforestry (ICRAF), following the recommendation of Bene et al. (1977). This was a response to the perception that tropical forests were increasingly threatened by agricultural expansion. Agroforestry research became a topic of major interest among agricultural scientists, at first centered on Africa and restricted to a small range of practices aimed at soil improvement. The term agroforestry has gradually been adopted in other disciplines, especially anthropology and geography, to cover the wider range of traditional polycultural systems which include trees. The literature on agroforestry is now enormous.

Deforestation in the tropics was one among a number of environmental concerns that in the last decades of the twentieth century prompted wide-ranging research on causes and rates of environmental change. Cultural, ecological, and historical aspects of human agency have been an important part of this research, which has at times fueled political controversy over issues such as indigenous rights and conflicting claims to resource use.

The expansion of archaeological and related research over the last few decades has made clear that human-environmental interactions are complex and variable across time and space. Simplistic developmental trajectories, based on hypothetical sequences of the practices by which human groups have drawn food and other resources from their environments, have been superseded by more complex local and regional sequences. These are based on a wide range of evidence from many disciplines, derived from a profusion of new, analytically sophisticated research techniques and revised research questions.

Recent research on tropical forests has shown that these are mostly not primeval remnants of an ancient, unpeopled world and that human impacts on them are not restricted to relatively recent degradation, nor are they inevitably destructive (Brookfield 2001; Bhagwat et al. 2008). There has been an upsurge of interest in traditional small-scale tropical forest farming systems, many of which can be described as agroforestry, drawing together descriptions in older literature with newly identified variants. Ethnobotanical studies have shown that local systems of plant management often articulate elements that lie outside common analytical conceptions of agroecosystems, thus extending the boundaries of human influence on vegetation across space and over time (influential examples are Yen (1974) for Oceania and Alcorn (1981) for Mexico).

Traditional, subsistence-oriented agroforestry systems encompass fixed, rotational, and shifting fields and may include trees for food, fuel, medicine, forage and other uses, as well as for soil improvement and erosion control. While there is a strong association with tropical rainforest, there are tropical savanna and temperate examples as well.

Among the most familiar agroforestry systems (though not usually so-described) is the archetypical palm-fringed tropical South Pacific island. Its traditional components, apart from coconuts, include iconic ornamentals such as hibiscus and gardenia, breadfruit, and other tree crops, along with root and herbaceous food crops. These Pacific farming systems have often been characterized as arboriculture (Yen 1974), emphasizing the tree crop component, which is certainly distinctive but nevertheless an integral part of the larger system (Clarke and Thaman 1993). Another classic exemplar of an agroforestry system is the Guatemalan orchard-garden minutely described and mapped by Anderson (1952: 137–40). And in northern Luzon, in the Philippines, Conklin's (1980) detailed research over many years on the monumental rice terraces of the Ifugao showed how they are embedded as one component, albeit overwhelmingly picturesque, of an intricately

managed and flexible landscape architecture in which "woodlots" are essential. These carefully managed mini-forests provide food, medicine, firewood, and construction materials but most importantly, anchor the water and soil that maintain the terraces (Conklin 1980; Brookfield 2001: 18–20).

The literature describing traditional systems of tree management in the tropical New World expanded rapidly during the 1980s and in Southeast Asia, especially Indonesia, in the 1990s (summarized in Brookfield 2001: 140–56). Regional surveys of modern agroforestry practices often begin with thumbnail accounts of past practices for which high antiquity is asserted (e.g., for China, Hsiung et al. 1995; and Europe, Eichhorn et al. 2006). Although it is commonly accepted that the widespread and varied traditional forms of agroforestry systems have considerable time depth, evidence of this is often weak. In a few areas, the detailed ethnographic and ethnobotanical descriptions of extant traditional agroforestry systems have attracted the attention of archaeologists and provided the impetus for research on the origins and development of these tree-based agroecosystems, using archaeobotanical and paleoecological evidence. Such research contributes to wider debates among archaeologists and others on Pleistocene to Holocene environmental change, human-environmental interactions in general, and trajectories of plant-based human resource use in particular.

Key Issues/Current Debates

Tropical rainforests, under increasing threat from the encroachments of the modern world, have become the focus of increased attention from many disciplines: ecology, climatology, biogeography, and the politics of resource use prominent among them. Rates of change, at all scales and time periods, are a critical and highly contentious issue, as are the nature and timing of human impacts. The recent upsurge of multidisciplinary interest has largely rewritten tropical rainforest ecology and has opened new debates in archaeology and historical ecology.

Most archaeological research on agroforestry and related systems has so far been concentrated in the tropics, especially the New World, where establishing evidence for plant food production is problematic. Tropical agroecosystems are a poor fit for standard theoretical frameworks concerned with agricultural origins, in which the sharp contrasts of foraging/farming and wild/domestic are supported by relatively well-defined domestication syndromes of annual seed crops (Fairbairn 2005). Systems based on these crops do not furnish comprehensive models of the much greater range of practices which produce foods from plants managed in modified environments. Perennial crops, especially those propagated vegetatively, have been largely overlooked in synthetic models linking domestication processes and landscape management (McKey et al. 2012). Because of their long life spans and slow growth, tree crops are an especially difficult category (Kennedy 2012). Recent research has begun to increase the range of plants examined, as new techniques in archaeobotany are more often applied, and comparative collections expanded.

Understanding the development of crop assemblages and agroecosystems has tended to be sidelined by research, especially recent genetic research, on individual crops. Current archaeological research on local and regional trajectories of prehistoric human resource use ranges in scale from the isotopic signatures of dietary histories of single individuals to cultural and environmental transformations over millennia. The complexity of new data requires very specialized technical skills and more sophisticated models than ever. The challenge to develop interdisciplinary collaborations, based on shared understanding of complex laboratory methods matched with the flexibilities needed for field research, has never been greater.

International Perspectives

Although agroecosystems that might be described as agroforestry exist virtually throughout the cultivated world, archaeological research on these has been concentrated especially in the tropics.

In temperate areas of the Old World, where research on the prehistory of agriculture has concentrated especially on the cereals, other crops, including trees, have tended to be considered species by species, if at all. Their integration as part of agroecosystems has been less of an issue than their incidental presence in cultivated landscapes.

Recent archaeological work in the New World has focused directly on agroforestry. In tropical Central America and Amazonia, there is an emerging consensus of widespread modification and more or less intensive management of forest, including successional fallows (reviewed by Brookfield 2001: 141–6). However, debate continues about the origins of particular crops, the directions and rates of spread of these, and the sequence of practices associated with their management.

Landscape-focused, multidisciplinary research on agroforestry and management of water resources around the Mayan site Tikal has recently been renewed (see "Further Reading", below). In western Ecuador, in a valley-wide study, Stahl and Pearsall (2012) drew together macrobotanical, phytolith, and faunal data from archaeological contexts to infer that pre-Columbian agroforestry was practiced, producing a managed landscape mosaic in which domesticated annuals were combined with perennial tree crops and useful forest taxa. In the Peruvian Andes, Chepstow-Lusty and Winfield (2000) used historical and ethnographic data along with pollen cores and archaeologically provenanced charcoal from fuel wood, to examine Inca management of trees for firewood, construction, and tool making. Their data imply that this management would also have protected water resources.

In the Pacific, the relatively rich ethnohistorical and ethnobotanical records of traditional agroecosystems of the small, remote islands, especially those of Polynesia, form a particularly striking paradigm of landscape transformation under human management. Most of the plant food resources of these islands are human introductions. Archaeobotanical and paleoecological research on these islands is increasingly directed to resolving local sequences that span both prehuman and human phases of environmental change and to disentangling human action from other causes of environmental change. Human agency here includes construction of agricultural features such as terraces and ponded fields and extensive tree planting as well as erosion and deforestation. Athens et al. (1996) considered development of the traditional agroforestry system of Kosrae, a Micronesian high island, using pollen, sedimentological, and macro- and micro-charcoal evidence derived from cultural and noncultural contexts. They argued that this system, in which the trees and other crops are introduced cultigens, was established rapidly after the first colonization and persisted relatively unchanged for nearly two millennia. In contrast, developmental sequences have been proposed for other remote Pacific islands, starting with shifting cultivation which is then gradually transformed by intensification of land use and management of the introduced tree crops.

Further west, on larger islands of the southwest Pacific, the time span of human settlement extends back to the Pleistocene. The extended trajectories of human resource use are enmeshed with the effects of late Pleistocene climate change and include transition from hunter-gatherer to agricultural economies and domestication of local plants as well as extensive landscape modification. On these large islands, cultivated and wild populations of closely related tree species coexist, often without easily defined boundaries between them. Ethnobotanical and other descriptions provide incomplete coverage of the very diverse agroecosystems, many of which are tree based (Kennedy 2012). Archaeobotany in these islands confronts the pioneering challenges of poorly specified models and inadequate reference collections (Fairbairn 2005). Archaeobotanical and other evidence for sequences of resource use is scarce, especially in the lowland areas of tropical rainforest. In the densely populated intermontane valleys of

highland New Guinea, the striking diversity of extant intensive agricultural systems reflects a long and complex prehistory. Haberle (1998) collated chronological data from 16 archaeological and 23 paleoecological sites across the highlands, showing indirect evidence of changes associated with agriculture over the last 2000 years. These include most notably an increase in pollen of *Casuarina*, likely to represent a nitrogen-fixing species (*C. oligodon*) widely planted today for firewood and construction, and recognized as having sacred/aesthetic value and as a soil improver. There are also changes in palynological and sedimentological data indicative of landscape disturbance. Tephra chronology and sequences of archaeological features articulate with the other records to show an overall picture of dramatic and widespread change. Since these changes are not synchronous across the highlands, Haberle (1998) suggests that they reflect human activities, including adoption of new crops and new management practices such as agroforestry, as well as climatically driven environmental change.

In Southeast Asia, the large literature describing extant systems of agroforestry is mentioned above. This record raises questions for archaeobotanical and paleoecological research that are yet to be addressed in any detail. The region suffers from much the same challenges of pioneering research as the large islands of the southwest Pacific to the east (Fairbairn 2005). In some areas, including the islands of Java and Borneo, it is commonly assumed that systems such as fallow management and household orchards are historically recent developments, but evidence for this is lacking (Brookfield 2001: 146–7).

In Africa, the literature on modern agroforestry systems is enormous, and the remedial interventions that this literature documents were first developed there. There is nevertheless recognition in this literature of the existence of traditional forms of agroforestry, though without much evidence for their antiquity. Archaeological studies have begun to remedy this. For example, Neumann et al. (2012) point out the widespread importance in archaeological sites, all over West and Central Africa from the semi-arid Sahel to the humid rainforest, of intensively exploited trees, especially those with oil- and fat-containing seeds and fruit, over at least the last 2500 years. Archaeobotanical and other records elucidating how and when these trees have come to be integrated with other crops are so far very limited. Some of the trees, notably oil palm (*Elaeis guineensis*), are now important crops on the world market. Genetic research to improve this resource is very likely to provide useful insights relevant to its past. As elsewhere, archaeological evidence for the origins and development of African traditional agroforestry systems needs more research oriented to archaeobotanical and paleoecological questions.

Future Directions

Since the role of human agency in environmental change is currently a subject of great interest, the extended time scale contributed by archaeological studies is likely to be increasingly valuable. Archaeological research based on multidisciplinary collaborations enables the investigation of complex linkages between patterns of human resource use and environmental change, encouraging the development of more sophisticated models than before.

Human use of plant resources is undergoing reassessment, as new techniques allow more direct and detailed data bearing on previously difficult questions, such as the constitution of individual diets, rates of genetic change of plants under human management, and fine-grained environmental fluctuations. As a result, existing models of the ecological relationships that underpin human subsistence are subject to renewed critique (e.g., Zeder 2012).

Insights from the extensive new research on agroforestry and related practices in the New World are likely to be influential and to stimulate similar work in other areas.

Aguigah, Angèle Dola

Didier N'Dah
Département d'Histoire et d'Archéologie, Université d'Abomey-Calavi, Abomey-Calavi, République du Bénin

Basic Biographical Information

Dr. Angèle Dola Akofa Aguigah (Fig. 1) is the first female archaeologist from Togo. She was born 4 December, 1955, in Lomé, Togo, where she grew up. Dr. Aguigah is the first female archaeologist in Togo and one of the only archaeologists in the region to defend two doctoral theses in archaeology. In 2007, Dr. Aguigah was admitted to the rank of Living Human Treasures of Togo.

Dr. Aguigah undertook her higher studies in France, where she obtained at the University of Paris I, Pantheon-Sorbonne, a License in Archaeology and general History of Art (1978–1979), a MA in African Archaeology (1980–1981), a Diploma of Advanced Studies (1981–1982), and a Ph.D. in African Archaeology (1982–1986) (Aguigah 1986). She also obtained a Certificate in Regional Planning and Urbanism from the National Arts Centre of Paris in 1992. In 1991, Dr. Aguigah started work on a second African Archaeology Ph.D. thesis, successfully defended in 1995 at the University of Paris I, Panthéon-Sorbonne, under the supervision of the late Professor Emeritus Jean Devisse (Aguigah 1995).

Aguigah, Angèle Dola, Fig. 1 Mrs. Angèle Aguigah

Dr. Aguigah is a Senior Lecturer at the Universities of Lomé and Kara (Togo) and also teaches art history at the School of African Architecture and Urbanism. She is the Head of the Archaeological Program of Togo and a consultant in cultural heritage. She has given courses in several universities in West Africa, France, and the United States of America. She has directed several archaeological excavations and her research on Notsé, Tado, Dapaong, Nook (Togo), and Bè sites is the subject of an exhibition at the National Museum of Lomé (Togo).

She has participated in several international conferences and scientific events and is a member of several associations and networks, including the UNESCO-Network Forum at the World Heritage Centre of UNESCO, the Council of African Museums, and the Board of Directors of the West Africa Museums Program. Dr. Aguigah's administrative duties include being Secretary-General of the Association of Heritage Friends, Lomé; Vice-President of Togolese ICOM (International Council of Museums), Lomé; President and member of the Togolese ICOMOS (International Council on Monuments and Sites), Lomé: and in 1999–2001 President of West African Archaeological Association (WAAA). She is still the current president of this Association (2013–2015). She is also President of the Network of African Women Ministers and Parliamentarians section of Togo.

Dr. Aguigah has received many decorations and awards during her career. Notable among these are the Order of Merit from the University of Lomé (1999); Knight of the French Order of Academic Palms (2002); Officer of the Order of Mono, Togo (2002); Award of Excellence at the University of Lomé (2005); and a Distinguished

Personality of the African Jubilee of Independence of Togo (2010).

Major Accomplishments

Dr. Aguigah's fieldwork across the Togolese territory has contributed to knowledge of the rich archaeological heritage of the country and to the protection and management of this heritage. One of her major accomplishments is rehabilitation of the archaeological sites of Notsé, Bassar, and Tcharè (Togo). As a consultant to UNESCO, she undertook an inventory of the intangible cultural heritage in Togo in 2008. She is currently coordinator of the ongoing study of the caves sites of Nook and Mamproug for their registration on World Heritage list of UNESCO.

Dr. Aguigah has occupied high positions in her country. She was Minister Delegate to the Prime Minister's Office in charge of Private Sector of Togo (2000–2003) and Minister of Culture of Togo (2003–2005). This last function enabled her to put her competences as an archaeologist to the service of her country. The concrete actions that she undertook included the presentation of the "Cultural Landscape of Koutammakou" and its registration in the World Heritage list of UNESCO, the first cultural landscape registered in Togo; realization of the first edition of "Heritage Month" in the Togo official launch of the site of Koutammakou; revaluation of endangered culinary heritage through the presentation of dishes in the maritime region, Aného; carrying out a study on the development of cultural industries and identifying opportunities for economic growth in Togo; creation of Regional Directions of Culture in the context of decentralization of culture in Togo; facilitation of an exhibition "Museum and Heritage Woman" at the artisanal center of Lomé for International Women's Day; meeting with tour operators and travel agencies on the socioeconomic management of heritage sites; and coordination of the cultural policy of Togo on an international level in the context of globalization, cultural diversity, and intercultural dialogue.

Dr. Aguigah has contributed to the training of several generations of archaeologists in West Africa. In addition, she has participated in important archaeological fieldwork particularly the excavations of the Loropéni ruins southwest of Burkina Faso, required for the registration of this site on the UNESCO World Heritage list in 2009.

'Ain Difla Rockshelter

Geoffrey A. Clark[1] and Joseph Schuldenrein[2]
[1]School of Human Evolution and Social Change, Arizona State University, Tempe, AZ, USA
[2]Geoarchaeology Research Associates, Inc, Yonkers, NY, USA

Introduction

'Ain Difla (WHS 634) was discovered by Burton MacDonald's Wadi Hasa Survey in 1982 and was partially excavated by Geoffrey Clark in 1984, 1992, and 1993; by Clark and Gary Rollefson in 1986; and by Zeljko Rezek in 2010 and 2011 (Fig. 1). Located at c. 780 m above sea level in the Wadi Ali, a southern tributary of the Wadi Hasa in west-central Jordan, the site consists of a small wedge of sediment preserved under the overhang of a large rockshelter, the contents of which have mostly been emptied by fluctuations in the course of the wadi, now located some 12 m below it. Intact deposits cover about 35 m^2 and extend to a depth of c. 6–7 m in the talus slope in front of the rockshelter (Fig. 2). Preservation within the rockshelter is a function of its location, nestled within a recessed cavity that protected it from lateral erosion and slope retreat.

Definition

Field profiles record approximately 30 thin, moderately sloping (7–15°) to subhorizontal layers or lenses in Tests A and B, which reached a depth of 2.1 m below datum. Excavation proceeded by 10 cm arbitrary levels (spits) because the natural stratigraphy of the extremely dry sediments was very hard to follow clearly. Three primary sediment "packages" comprise (1) surface debris, roof

'Ain Difla Rockshelter, Fig. 1 A plan view of the 'Ain Difla rockshelter (WHS 634): units excavated during the 1984, 1986, and 1992 field seasons in Tests A, B, and C. (After Clark et al. 1997: 80)

'Ain Difla Rockshelter, Fig. 2 View of 'Ain Difla from the south bank of the Wadi Ali showing the locations of Tests A–C, the high (12–30 m) and middle (3–7 m) terraces, and the present wadi floodplain (foreground). A linear pile of boulders from a major collapse of the shelter overhang can be seen to the left. The position of these rocks indicates that the shelter overhang extended at one time at least 10 m beyond its present location. (After Clark et al. 1997: 78)

spall, deflated silts, and pockets of calcreted organic residues (0.0–0.6 m); (2) organic silts and oxidized sands associated with weathering and water-laid (possibly seasonal) sedimentation (0.6–1.4 m); and (3) more consolidated flowstones and breccias interstratified with organic lenses that accumulated episodically and were subsequently calcified (>1.4 m).

A geological section, Test C, was excavated to a depth of 7 m below datum to determine the relationship of the rockshelter fill to the high (12–30 m) and middle (3–7 m) terraces of the wadi. It showed that, although scattered artifacts occurred in fragments of both terraces, relatively intact cultural deposits backed up against the shelter wall were confined to the talus slope fronting the site. Six primary depositional units were recognized, variously subdivided. The lowest part of the sequence rests on what appears to be a fragment of the middle terrace and consists of alluvial sands and silts, gravel stringers, and local slope wash (units 6–4A). Unit 3B records an episode of brecciation, and the upper part of the sequence consists of slope collapse, scree, mixed colluvium, rubble, and roof spall (units 1–3A).

Northwest of the rockshelter, three massive blocks of tufa (calcium carbonate precipitates) cover the mid-slopes of the Wadi Wanid, a tributary of the Ali. The base of the highest of these lies at approximately the same elevation as the upper third of the occupation levels in the rockshelter and is thought to be roughly contemporaneous with it. Dated to 141 ± 20 ka BP, it represents an ancient spring that could have recharged the aquifer that fed the active wadi systems during the Upper Pleistocene prior to the cut and fill sequences registered in the middle and low (0.5–1.5 m) terraces (Fig. 4).

'Ain Difla is a Middle Paleolithic (Mousterian) site dated by 10 thermoluminescence (TL), thorium/uranium (Th^{230}/U^{234}), and electron spin resonance (ESR) determinations to 180–90 ka BP. The site was assigned to the Middle Paleolithic based on the absence of any later materials in the initial surface collection (1982) and the presence of elongated Levallois points. The excavations produced an assemblage of 19,132 stone artifacts, one of the largest from the region. Statistical descriptions of the lithic assemblage using standard Bordesian indices and ratios, a use-wear study of a sample of the Levallois points, the stratigraphy, sedimentology, landscape geomorphology, paleontology, and palynology, have been published (Lindly and Clark 1987, 2000; Clark et al. 1987a, b, 1997; Schuldenrein and

Clark 1994, 2001, 2003; Mustafa and Clark 2007).

Although samples were taken from the entire sequence, pollen was recovered only from Levels 1 and 3. These layers are dominated by non-arboreal taxa indicating steppe vegetation (Chenopodiaceae, Tubuliflorae, Artemisia, Gramineae, Cruciferae), suggesting that the last phase of occupation took place during a cool, dry interval, perhaps MIS 6 (186–127 ka BP): or the early part of MIS 5 (121–27 ka BP). A TL determination from Level 5 (105 ± 10 ka BP) dates the latest possible occupation at 'Ain Difla because the pocket of sediment that constitutes the site extended up to within about 50 cm of the shelter overhang.

Faunal analyses are also consistent with a cool, dry, steppe environment. The sparse assemblage is largely confined to teeth and is dominated by equids (wild ass, horse, or possibly, zebra – *Equus hemionus/asinus*; *Equus* sp. indet.) and caprids (goat or ibex – *Capra* spp.) but gazelle (*Gazella* sp. indet.) are also present. Grassland grazers, gazelle and equids (three species) are indicators of steppe or steppe/desert conditions, consistent with the dry conditions indicated by the pollen.

Technological, typological, and metrical analyses of the 'Ain Difla lithics are consistent with previous studies that align 'Ain Difla with the Tabūn D-type Levantine Mousterian. First defined by Dorothy Garrod at Mugharet et-Tabūn, a cave on Mt. Carmel, Tabūn D-type assemblages are typically made on laminar blanks (blades, elongated points) derived from Levallois and non-Levallois unipolar convergent and bipolar cores (Fig. 3). Based on core reconstructions, Meignen (1994) notes a change in the volumetric concept of reduction that differs little from that of Upper Paleolithic blade industries. Tabūn D assemblages often contain a higher frequency of retouched pieces when compared with those assigned to Tabūn C and B. Bifaces are usually absent, and those reported by Garrod at Tabūn layer D could have resulted from mixture with uppermost Layer E, assigned to the Acheulo-Yabrudian (Bar-Yosef 1998). Tabūn D-type assemblages are reported from Tor Abu Sif and Sahba, in the Judean Desert; at Rosh Ein Mor and Nahal Aqev 3, in the central Negev highlands; in the Galilee at Hayonim lower layer E; at Jerf Ajla and Douara Cave layer IV, in the Palmyra Basin; the Hummalian sites at El Kowm, in Syria; and at the 'Ain Difla rockshelter, in west-central Jordan. TL and ESR dates from Tabūn and 'Ain Difla indicate temporal spans of 270–170 ka BP (Mercier et al. 1995) and 184–90 ka BP (Clark et al. 1997) respectively, suggesting that human use of the site falls in the latter half of the Levantine type D Mousterian chronology. No human fossils have so far been recovered from any D-type site, so the authors of this Mousterian facies remain unknown. Neanderthals have been found in association with Type B industries at Kebara and Amud and with Type C industries at Tabūn, whereas early modern humans are associated with Type C industries at Qafzeh and Skhūl. Although dated sites are few, there is general agreement that the D-type

'Ain Difla Rockshelter, Fig. 3 A schematic NW/SE section through the 'Ain Difla rockshelter showing gross stratigraphy in relation to bedrock and to what is probably the middle terrace of the Wadi Ali – not drawn to scale. (After Clark et al. 1997: 79)

'Ain Difla Rockshelter, Fig. 4 A schematic NNW/SSE section through the cuesta ridge separating the drainages of the Wadi Ali and the Wadi Wanid – vertical scale exaggerated. (After Clark et al. 1997: 80)

industries mostly predate the last interglacial (MIS 5, 127–71 ka).

Although Middle Paleolithic sites are fairly common and well-published west of the Jordan Rift (see, e.g., Bar-Yosef 1998), stratified Middle Paleolithic sites in Jordan are confined to 'Ain Difla, and to Tor Sabiha, and Tor Faraj rockshelters in the Wadi Hisma below the Ras en'Naqb escarpment in southern Jordan (Henry 1995, 2003), and the open-air sites of Ar Rasfa on the eastern edge of the Jordan Rift in the northwest part of the country (Ahmad and Shea 2009) and WHS 621, at the eastern end of the Wadi Hasa (Clark et al. 1987).

Except for a very low incidence of retouched pieces (1.1%), 'Ain Difla is in good agreement with descriptions of the Levantine Type D Mousterian. Typological and technological comparisons with other Levantine Mousterian sites suggest that the evolution of the blade-rich Mousterian can be viewed as a continuum between the early (Tabūn) and late (Boker Tachtit) Mousterian, that (on any index) 'Ain Difla falls somewhere around the middle of that continuum, and that after about 47 ka BP, Mousterian laminar technologies develop more or less continually into the early Upper Paleolithic Ahmarian. It might also be the case that blade-dominated industries long predate the Mousterian itself, extending far back into the Lower Paleolithic (Monigal 2001).

Key Issues

'Ain Difla derives its importance from several aspects of modern human origin (MHO) research in the Levant and from an ongoing debate about the compositional integrity and behavioral implications of the basic analytical units used there, the Mousterian facies defined by Garrod at Tabūn.

MHO research in the Levant is guided by two conceptual frameworks that, in their extreme forms, are almost diametrically opposed to one another: (1) the multiregional continuity (MRC) model (e.g., Wolpoff et al. 2000) and (2) the recent African origin (RAO) or replacement model (e.g., Stringer 2007). MRC advocates emphasize strong evidence for continuity in adaptation based on fossils and on archaeology and supported by studies of symbolic and mortuary behavior. MRC holds that archaic *Homo sapiens* evolved independently into anatomically modern humans in the Levant and elsewhere, that gene flow through interactions between neighboring groups was sufficient to maintain species integrity over large areas, and that differences between archaic and modern *H. sapiens* are subspecific or populational, rather than specific. RAO emphasizes the results of genetic analyses of human mitochondrial DNA and "spread-and-replace" scenarios drawn from certain construals of pattern in the archaeological record. RAO maintains that

anatomical moderns arose as a speciation event in an isolated region of east Africa and that they migrated, radiated, or dispersed from Africa throughout Eurasia after c. 100 ka, eventually replacing all other archaic hominins over the range originally colonized by *Homo erectus*.

'Ain Difla is important in MHO research because evidence from the site supports Jelinek's arguments for local continuity in cultural development at Tabūn (e.g., Jelinek 1981). At neither site are there any indications of obviously intrusive elements, as would be expected under the RAO models proposed by Stringer (e.g., 2007) and others. The core tenet of the RAO model is that if anatomically modern African immigrants were moving into the Levant and replacing indigenous archaic populations there, that process should be evident in the appearance of a distinctive cultural repertoire, with an archaeological "signature" that differs from that of the indigenes and that it should be discernible in differences in adaptation between archaic and modern populations. While changes in technological continuity are not necessarily related to changes in human morphology, continuity in adaptation as monitored by the archaeology tips the balance in favor of multiregional continuity as the hypothesis best supported by the available evidence (Mustafa and Clark 2007).

The 'Ain Difla research is also noteworthy in an epistemological sense because work there has had important implications for pattern in the Levantine Mousterian and what it might mean in terms of human behavior. The large collection from the site has been compared to those from 19 other Levantine sites classified by reference to the 3-facies sequence at Tabūn (Culley et al. in press). Keeping in mind that 'Ain Difla is only a small part of a much larger site, now destroyed, the work showed that human occupations were ephemeral and episodic, of short duration, by small numbers of people and that there was little evidence for prolonged use of the locality. A dozen small circular or oval hearths attest to visits by perhaps three to six individuals, a pattern most consistent with an overnight hunting camp by a small party dispatched for some particular purpose from a larger residential base located elsewhere. There is little evidence for core preparation, primary and secondary reduction, and almost no retouched pieces, indicating the provisioning of mobile individuals with a limited number of tools they could carry with them, rather than the full repertoire of lithic processing activities expected at a long-term residential base.

Work at 'Ain Difla is ongoing, with current efforts directed toward refining the radiometric chronology of the upper sequence using optically stimulated luminescence (OSL) dating of sediments from Levels 1–5.

Aitken, Martin

Michael Tite
Research Laboratory for Archaeology and the History of Art, University of Oxford, Oxford, UK

Basic Biographical Information

Following a B.A. in physics and a D.Phil. in high energy physics at the University of Oxford, Martin Aitken (1922–2017) was appointed in 1957 as the Deputy Director of the Oxford Research Laboratory for Archaeology and the History of Art which had been established 2 years earlier through the combined efforts of Lord Cherwell and Professor Christopher Hawkes under the directorship of Edward (Teddy) Hall. Martin Aitken then continued to work at the Oxford Research Laboratory until his retirement in 1989.

Major Accomplishments

In the early days, his two main research interests were magnetic dating and magnetic prospection, of which the former remained an ongoing interest throughout his career. Initially, magnetic dating involved the measurement of the past direction of the Earth's magnetic field using large samples extracted from in situ kilns and hearths, but later, the method was extended to the measurement of the past intensity of the magnetic field, an approach that did not require in situ samples but could be applied to pottery sherds. Although as a dating method, the technique never realized its initial expectations; the results have helped toward our understanding of the origin of the Earth's magnetic field and are thus an example of the contribution of archaeology to science rather than vice versa.

In 1958, he undertook the first successful magnetic survey on an archaeological site using a proton magnetometer which had been developed and built in the Oxford Research Laboratory. Originally developed to locate kilns for magnetic

dating, it was immediately found that the proton magnetometer could also be used to detect filled-in pits and ditches, as well as stone walls surrounded by topsoil. Thus, the very considerable potential of magnetic prospection for the investigation of archaeological sites prior to excavation was established, and as a result, magnetic prospection, using various types of magnetometer, is now extensively used on archaeological sites throughout the world.

One consequence of his involvement in magnetic prospection was the emergence of the International Symposium on Archaeometry. In 1962, he organized a course for archaeologists who had purchased proton gradiometers from the Oxford Research Laboratory. During subsequent years, regular reunions of these gradiometer users were held in Oxford, and gradually the scope of these reunions expanded to include other aspects of archaeometry until eventually they evolved into the annual (now biennial) International Symposium for Archaeometry, of which the 42nd symposium was held in 2018. From their inception, he was Chairman of the Standing Committee responsible for their organization, subsequently, from 1990 to 2008, taking on the role of president.

In 1960, he initiated the first detailed research into the use of thermoluminescence (TL) phenomena for the dating of archaeological ceramics. Subsequently, luminescence dating was his primary research interest through until his retirement and beyond. Thus, he was actively involved in all the wide-ranging developments that occurred from its beginnings as a method for dating and authenticating ceramics, through TL dating of burnt flint and calcite deposits in caves, to the development of optically stimulated luminescence (OSL) dating of sediments. Again, the first Specialist Seminar on Thermoluminescence Dating that he organized in Oxford in 1978 evolved into the current triennial International Conference on Luminescence and Electron Spin Resonance Dating, of which the 15th conference was held in 2017. As a result, he established the Oxford Research Laboratory as an internationally recognized center of excellence for luminescence dating.

In addition to more than 150 scientific papers, he published the first comprehensive textbook on archaeometry, entitled *Physics and Archaeology* (1961, Interscience Publishers, London). Subsequently, as well as a second edition of *Physics and Archaeology* (1984, Clarendon Press, Oxford), he published books entitled *Thermoluminescence Dating* (1985, Academic Press, London), *Science-Based Dating in Archaeology* (1990, Longman, London), and *An Introduction to Optical Dating* (1998, Oxford University Press, Oxford). In addition, until 1989, together with Professor Edward Hall, he edited the journal *Archaeometry* from its humble beginnings as the Bulletin of the Oxford Research Laboratory to its current status as one of the primary international journals for the subject. He has further contributed to the development of archaeometry through his supervision of a succession of research students, several of whom have continued to work in the field and become authorities in their own right.

Recognition of his contribution to the subject both nationally and internationally came: first, in 1983, with his election as a Fellow of the Royal Society and, second, in 1985, when he was given an ad hominem Chair in Archaeometry by the University of Oxford.

Thus, throughout his career, Martin Aitken has been at the forefront of research in archaeometry and has played a major role in ensuring the subject's national and international recognition within both the archaeological and scientific communities. Therefore, he can be truly seen as one of the "fathers" of archaeometry, even though, having confined his research to scientific dating and prospection methods, he has always regarded himself as being primarily a physicist rather than an archaeological scientist.

Akrawi, Aysar

Aysar Akrawi
The Hashemite Kingdom of Jordan, Petra National Trust, Amman, Jordan

Basic Biographical Information

Aysar Akrawi's educational background is in history and political science, and she has undergone extensive training in senior management. Previous positions have included setting up and managing The Queen Noor College for Civil Aviation and introducing and implementing entrepreneurial projects for women in rural areas of Jordan.

Major Accomplishments

Aysar Akrawi has occupied the position of executive director of the Petra National Trust (PNT) since 1994. In this capacity, her responsibilities are diverse. As it is the aim of the Trust to advocate for the preservation of the cultural and natural heritage as well as the integration of the local communities in the decision-making process of the PAP and the Petra region, she is responsible for the planning, implementation, and supervision of the Trust's projects; the local and international publications; and coordination with governments, other NGO's, international donors, and international preservation organizations and societies. Finally, she is also responsible for the correlation with the media, educational systems, and action groups with the purpose of increasing public awareness of the World Heritage Site of Petra.

One of PNT's major roles throughout Aysar Akrawi's tenure has been advocacy for protection of Petra and its associated Outstanding Universal Values.

PNT has called for maintaining a rational balance between the dictates of the site's fragile environment and the role of tourism in the region's economy. Community involvement in the development and protection of this important heritage remains a high priority for PNT.

A major mechanism for this inclusion is the Petra Junior Ranger Programme, in which youth from the communities surrounding Petra learn about the site and its significance to their heritage. This project raises awareness among future decision makers, arming them with important knowledge and skills. Additionally, PNT has implemented conservation projects with local, national, and international partners that save both monuments and lives. The PNT furthermore pivotally serves as the institutional memory of developments in the state of management and conservation of Petra.

Aksum: Environmental Archaeology

Federica Sulas
Centre for Urban Network Evolutions, Aarhus University, Aarhus, Denmark
Anthropology and Archaeology, University of Pretoria, Pretoria, South Africa

Introduction

Rising above the Sudanese lowlands to the north and the Red Sea coastal plains to the east, the highlands of northern Ethiopia and Eritrea have long been recognized as a center of plant domestication and host of some of the earliest complex societies of sub-Saharan Africa. The intensification of contacts with southern Arabia in the first millennium BCE favored the development of complex societies and, later, the emergence of the Kingdom of Aksum (c. BCE 140–CE 800). Aksum is located on a gentle plain at the heart of the Tigray highlands (Fig. 1) which provided excellent ground for the new kingdom to thrive for almost a 1000 years by engaging in long-distance trade and commerce, developing literacy and coinage. The adoption of Christianity in the early fourth century CE furthered Aksum's importance within and beyond northeast Africa. This historical significance has fostered intensive archaeological research in the region, but the history of its diverse environment has received little scholarly attention until recently. Today, Aksum (UNESCO World Heritage Site, 1981) is one of the most important archaeological sites of Africa and remains the leading religious center for the Ethiopian Orthodox Church. As environmental archaeology in Ethiopia and Eritrea grows, the historical contexts of landscape change are becoming increasingly prominent in current debates about land degradation and sustainable resource uses.

This essay presents an updated review of environmental archaeology at Aksum as appeared in the first edition of the *Encyclopedia of Global Archaeology* (2014). While the original framework offered then has not changed, the last couple of years have seen the publication of few important syntheses and studies that provide new stimuli to advance knowledge, and research, on human-environment interaction in the greater Aksum area in the coming years.

The essay first outlines the environmental aspects that have been explored by archaeological research at Aksum. The historical background traces the emergence of archaeological research through three main phases: the "discovery" (1900s–1940s), the "consolidation" (1970s–1980s), and the "diversification" since the early 1990s. A third section explores the emerging critique of environmental history models in the light of new research findings and changing perspectives. The review ends with a remark on the emphasis on the role of environmental archaeology and history to current debates on heritage management, land degradation, and sustainable resource use and some considerations on future research prospects.

Definition

Environmental archaeology in the northern highlands of Ethiopia has focused on three main topics: (1) the development of settlement and its impact on the landscape, (2) the availability and management of environmental resources such as

Aksum: Environmental Archaeology, Fig. 1 Map of Aksum: (*top row*) regional map and the location of Tigray; (*bottom row*) the Aksum area (contours are at 20 m interval)

land and water, and (3) the legacy of past land uses into present-day landscapes and societies. The emphasis on these topics is much the result of advances in archaeological methods and the sociopolitical transformations that have shaped modern Ethiopia and Eritrea. Intensive archaeological survey and reconnaissance records have elucidated the main patterns of settlement history in the Aksum plain. However, while the research focus on the development of the kingdom has produced well-defined settlement trajectories for the first millennium CE, the records for the periods before the emergence of Aksum and following its decline are patchy, and there are important gaps. For example, excavations at rock-shelter sites have detailed later prehistoric occupation sequences (c. ninth/eight millennia BCE) in the hills surrounding the Aksum plain (Phillipson 2000), but the landscape that hosted these early groups is poorly understood. In fact, no solid environmental record is available from Aksum for this period, though regional and continental

datasets of past climate are available. The regional record of significant climate amelioration at the beginning of the Holocene (c. 10,000 BCE) has been linked to the peopling of the area – though sporadic occurrences of Early Stone Age and Middle Stone Age material point to much earlier frequentation. Substantial environmental records are available only for the Aksumite periods, broadly encompassing the rise of social complexity and the demise of the kingdom (c. 900 BCE–CE 800). Studies of plant and animal remains and geoarchaeological investigations have contributed to illuminating aspects of the subsistence base of the kingdom and its impact on the landscape. Archaeobotanical and zooarchaeological studies have concentrated on settlement sites and funerary contexts, and geoarchaeological data come mainly from landscape sequences and buried soils (or paleosols). Regional climatic records provide further sources of information, but the physical diversity of the northern Ethiopian-Eritrean highlands together with patchy archaeological records makes it difficult to build solid correlations (see below). The cultural and environmental history following the decline of the Aksumite kingdom (c. 800 CE onward) is poorly understood, but there is now indication that Aksum's countryside was not abandoned (Fattovich 2008; Sernicola 2017). In addition, buried soil records, palaeobotanical data, and historical sources provide supporting evidence for prolonged settlement and arable land use throughout the second millennium CE.

Over the last decade or so, the implications of environmental reconstructions beyond archaeological research have begun to emerge. Geomorphological and land evaluation studies have often linked past land uses to present environmental degradation (e.g., Nyssen et al. 2004). The links between intensifying agriculture and the decline of the Aksumite kingdom feed into discussions about traditional land uses and their contribution to present environmental conditions. This remains a debated topic, which is unlikely to find consensus until a far more coherent and richer body of data is available. In fact, while Aksum is arguably the place where most archaeological research has taken place, environmental and land evaluation studies have targeted other areas of the Ethiopian-Eritrean highlands and beyond. Thus, correlations between local archaeological evidence and regional environmental proxies rely on questionable geographical, cultural, and temporal uniformities.

Historical Background

Discovery (1900s–1940s)

Archaeological investigation at Aksum begun in the early 1900s with the Deutsche Aksum-Expedition (hereinafter DAE) led by Enno Littmann. The German team comprehensively recorded ancient monuments at Aksum and other sites of Tigray and Eritrea. The detailed analysis of ancient architecture, inscriptions, and material culture was published in four volumes (Littmann et al. 1913) and laid the foundations of Aksumite archaeology. Although this team was not particularly concerned with environmental aspects, the expedition's photographic archive includes several panoramic views of Aksum's landscape in 1906 and, thus, before the occurrence of main reforestation programs, infrastructure building, and urban development, which later transformed significant parts of the Ethiopian highlands. This is a remarkable source of information that remains largely untapped. The DAE publication offered the first detailed description of the local archaeology, which Carlo Conti Rossini (1928) framed within a coherent historical context and linked to textual and oral sources. This includes, for example, reference to oral traditions linking the "fall" of Aksum to the destruction caused by the external invasions, droughts, and famines. However old some of these local traditions may be, they are preserved in manuscript texts, often compiled in much later periods than those to which they refer. That said, these sources offer remarkable information on Aksum's landscape, and some have long been referenced in support of archaeological interpretation (see Fattovich 2008).

In the 1930s and 1940s, systematic excavations at Aksum included the recording of landscape stratigraphy. In 1937, while in Aksum for the relocation of a stele to Rome, Ugo Monneret

Aksum: Environmental Archaeology, Fig. 2 View of Aksum's landscape, November 2007: taken from Beta Giyorgis hillside, near "D site," and looking northward. (Photo: F. Sulas)

de Villard (1938) conducted a topographic study and investigated the stratigraphic sequence of the Aksum plain. He identified two main phases of sediment depositions next to the Cathedral Maryam Seyon (Fig. 2): the earliest phase would have preceded the rise of Aksum, and, in particular, it would have occurred before the erection of the monoliths at the Northern Stele Park; a second phase would have taken place after the decline of the kingdom. Shortly afterward, further sedimentary data were collected by Salvatore Puglisi (1941), who led the *Missione Archeologica Italiana* at Aksum and sought to expand research beyond the then known archaeological area by surveying other sectors of the plain. Puglisi excavated a main residential building and conducted test excavations to the west and northeast of the old town where he recorded a stratigraphic sequence of cultural layers interspersed by alluvial deposits (Fig. 2). In the 1950s and 1960s, the newly established Ethiopian Institute of Archaeology (Addis Ababa 1952) sponsored further systematic research by French scholars who excavated important monumental structures and sites. The results of these studies provided new evidence for outlining the early cultural sequence of Aksum and its surroundings (e.g., de Contenson 2005).

Consolidation (1970s–1980s)

The early 1970s saw the beginning of large-scale excavations and surveys at Aksum and its surroundings by British, Italian, and American archaeologists. The new research programs were designed to examine the environmental factors and cultural processes involved in the development of the Aksumite kingdom (e.g., Munro-Hay 1989; Ricci 1990; Michels 2005). However, these were cut short by widespread sociopolitical unrest that culminated in the demise of the Ethiopian monarchy in 1974 and the establishment of the Derg regime (1974-1991). The new political setting halted field research for nearly two decades, but this interruption provided time for elaborating and publishing the results of the research conducted in the early 1970s. In particular, two main works laid the foundations for subsequent modeling of the environmental and settlement history of Aksum. In 1972, Butzer (1981) had conducted preliminary geoarchaeological

investigations in the Aksum plain, which included the application of soil micromorphology. The results were elaborated into an "archaeo-sedimentary" sequence that provided for the first time an integrated framework for linking cultural developments and environmental change. Although the chronological frame available in the 1970s was later revised, Butzer's sequence remains the main reference point for any environmental reconstruction of the Aksum area. The analysis of several sections in the core archaeological area (Fig. 1) led Butzer to conclude that four aggradation phases had occurred at Aksum. The first aggradation phase (c. BCE 150-CE 150) was associated with a period of increased precipitation and the growth of Aksum as a regional political center. The second aggradation phase was linked to the erosion of degraded agricultural lands upslope due to heavier rains coupled with settlement and demographic increase. The last two phases of aggradation occurred several centuries after the decline of the Aksumite kingdom.

Shortly after Butzer's work at Aksum, an American team led by Joseph W. Michels conducted a systematic survey of the region comprised between Aksum and Yeha (Fig. 1). During the 6 months of intense fieldwork, the survey documented over 250 ancient sites, and the resulting database not only included archaeological information but also a new classification of settlement types and records of modern land uses (Michels 2005). The results of this work (2005; an interim report was published in 1984) were fundamental in showing the intensity of ancient settlement over a diversified environment and the links between landscape characteristics and land uses.

Diversification (Since the Early 1990s)

Following the establishment of the Federal Democratic Republic of Ethiopia in the early 1990s, the country regained enough political stability for resuming archaeological fieldwork. New research programs began investigating the development of farming and livestock holding, the settlement system and subsistence base of the Aksumite kingdom, and the short- and long-term impact of land use practices on the environment. In 1993, two large-scale archaeological projects started at Aksum: David W. Phillipson (2000) led the British Institute in Eastern Africa's research in the plain, and the Italian-American expedition directed by Rodolfo Fattovich and Kathryn A. Bard resumed research on the adjacent hill of Beta Giyorgis (Fattovich et al. 2000). In addition to sharing a multidisciplinary approach, both projects combined large-scale excavations and systematic surveys for over a decade, and, thus, they ensured an unprecedented continuity of research. The British expedition excavated a number of sites to the north and west of the town. The excavations of rock-shelter sites clarified aspects of later prehistoric occupation, and research on later periods included the excavations at Aksumite sites and, significantly, the first rural settlement known as "D site" (domestic site). This low-status satellite farming settlement was located to the north of the old town (Figs. 1 and 2) and yielded evidence for two distinct occupations: an early farming-based settlement (c. 700–400 BCE) and, after a significant hiatus, a lower-status occupation in the sixth century CE. Botanical and faunal assemblages revealed a widening of the resource base from the early phase and included the first appearance of African cereals such as tef (Boardman 1999; Phillipson 2000). The records from "D site" and other sites nearby show that Near Eastern and African crops were grown from at least the mid-first millennium BCE and possibly earlier (Bard et al. 2000; D'Andrea 2008). Near Eastern plants (i.e., barley, emmer wheat, flax) were the most common groups and were most likely associated with dry farming. Since the mid-first millennium CE, there is evidence for an increase in food plants, cereals, pulses, oil, and fiber plants (Boardman 1999). With the exception of few species (grape, sorghum, finger millet), there is a remarkable continuity between the later Aksumite times and today (Phillipson 2000: 420). A similar scenario is illustrated by the results of exploratory pollen analyses on archaeological sediments from Beta Giyorgis hill, which point to the presence of an open grassland vegetation cover with tree patches from the mid-first millennium BCE (DiBlasi in Bard et al.

2000). While further palynological studies have yet to be undertaken, research on plant resources and vegetation history has gradually diversified. Recent developments include ethnobotanical approaches to reconstruct crop processing and taphonomic processes (D'Andrea 2008) and analyses of phytoliths and charred wood, from buried soils and sediments to acquire information on the vegetation history (French et al. 2009; Sulas 2016). As for zooarchaeological studies, the faunal assemblages from settlement sites at Beta Giyorgis and Aksum show a predominance of domesticated mammals (cattle, sheep, and goat), suggesting that animals were kept for meat, by-products, and labor (Bard et al. 2000; Phillipson 2000). These first studies showed the potential of zooarchaeology for investigating environmental and resource use aspects of the Aksumite culture. However, no further research in this direction has been conducted, and, in the absence of taphonomic studies, the role and use of animal resources remain poorly understood. Recent detailed analyses of lithic assemblages, instead, have added significant depth to understanding of the early peopling and resource management history of the Aksum area and the wider region in general (Phillipson 2009, 2017). Comparative studies of lithics by L. Phillipson (2017), in particular, have elucidated how rural population from the later prehistoric period has adapted to changing cultural and economic circumstances before and during the Aksumite period.

The last few years have witnessed the rise of the first Ethiopian archaeologists working at Aksum (Hagos 2001, 2010; Wurku Derara 2015) and the opening of the first archaeology department in the country (2006) at the newly established Axum University. New research projects were set up to investigate the local landscape history by combining geoarchaeological, palaeobotanical, and remote sensing techniques (Schmid et al. 2008; French et al. 2009). At the same time, Fattovich (2008), Sernicola (2017), and Phillipson (2009, 2017) resumed systematic surveying to complete the archaeological map of the greater Aksum area as well as conducting high-resolution studies of material culture (Fig. 3). Other recent studies also include geo-pedological research on past soil erosion (Ciampalini et al. 2008). As detailed in the following section, these new developments provide the basis for rethinking a series of aspects concerning the theories and methodologies of environmental archaeology in the region.

Key Issues/Current Debates

Recent research advances call now for a reconsideration of a series of long-established ideas about Aksum's past. First, new archaeological findings indicate the presence of agropastoralists in the Aksum area, and the northern Ethiopian highlands in general, since the mid-fourth millennium BCE at least (Phillipson 2017 and reference therein). It is also now apparent that a mosaic of cultures and subsistence strategies populated the region during the first millennium BCE (Phillipson 2012). This evidence calls for a rethinking of former cultural sequences emphasizing the importance of a single culture (viz., the pre-Aksumite culture) and farming. While these were part and parcel of Aksum's development as a kingdom, other cultures and ways of life played important roles in the broader region that was later under the control of the Aksumite kingdom. Second, there are substantial temporal and spatial discrepancies between the archaeological and landscape data at regional and local scale. A wide range of regional data about past environment and climate come from lake deposits and landscape sequences in areas and regions (see, e.g., Nyssen et al. 2004) for which archaeological evidence is very limited, if not absent altogether. On the other side, the remarkably rich cultural record from Aksum has been associated with limited local landscape data until recently; these were almost exclusively based on Butzer's "archaeo-sedimentary" sequence, linking the rise and demise of Aksumite cultures to increased rainfall, population growth, and intensified land use. Since the mid-1990s, the study of plant and animal remains and, more recently, geoarchaeological research have provided new local data that suggest a more complex scenario. Studies of plant macro- and microfossils

Aksum: Environmental Archaeology, Fig. 3 Archaeologists at Aksum, May 2006: top from left Charles French, Rodolfo Fattovich and Marco Madella; bottom Laurel Phillipson and Luisa Sernicola. (Photos: F. Sulas)

(seeds, charred wood, pollen, and phytoliths) indicate the presence of a woody savannah vegetation cover at Aksum before, during, and after the kingdom was in place, and there is no evidence for the occurrence of woodland and, subsequent, land clearance. This is further illustrated in the sedimentary record from the hilltop of Beta Giyorgis, hillsides, and river valleys north of the town (Fig. 1), reflecting prolonged landscape stability associated with permanent settlement and land uses from the mid-fourth millennium BCE until about 1600 CE (French et al. 2009). On hilltops and uplands, thick buried soil horizons were associated with settlement and farming, while buried soil records from hillside deposits may have been linked to pastures. The botanical remains (phytoliths and charred wood) from the buried soils reflect a substantially stable woody savannah

vegetation cover with tree patches nearby watercourses and settlements, of which palm trees were a significant component. However, the impact of the climatic fluctuations on the vegetation is still unclear, and the possibility of localized, intense, and climate-driven events, such as natural fires and the partial removal of vegetation by erratic rainfall, requires careful consideration. The buried landscape records have also prompted a revision of earlier models linking land productivity to irrigation at ancient Aksum. Yet, the buried soil record shows no evidence for irrigation, and the botanical indicators reflect the presence of crops and other plants that can grow under rain-fed farming (Boardman 1999; D'Andrea 2008; Sulas 2014).

Today, Ethiopia is undergoing major landscape transformations due to urban development and agricultural programs, and these changes are having a significant impact on the "traditional" lifestyles of the rural population. Modern Aksum is situated in a buffer position between international borders, a war-prone zone where rain/crop failure and political instability are actual rather than potential threats. A main theme of current research targets precisely the debate about present-day landscape conditions: Are they the results of mismanagement since people permanently settled down, started farming, and ultimately transformed Aksum's landscape? Or have both human and natural forces contributed to change? If so, what lesson can be learned from the past? These questions highlight the need for studies designed to understand the interrelated histories of land use and degradation not simply for writing Aksum's history but also for negotiating current challenges to heritage preservation and management (Wurku Derara 2015). As outlined above, archaeological research has long focused on the development of settlement and the emergence of social complexity, and only a limited number of studies have addressed the potential effects of agriculture and other land uses on the landscape. These are now emerging themes for understanding but also assessing and conserving Aksum's long-lasting environmental and cultural heritage.

International Perspectives

Since the early 1980s, the decline of the kingdom in the late first millennium CE has been linked to environmental degradation due to population pressure, arable land use intensification, and increased precipitation. This thesis has then been integrated with large-scale survey data on settlement patterns and applied for modeling a cultural history of Aksum, whereby human-induced factors inhibited landscape readjustments to climatic shifts. However, recent work has begun to question a number of assumptions based on earlier research. First, recent large-scale landscape investigations using a variety of archaeological science techniques are now regularly able to elucidate finer details from buried landscapes that indicate intrinsic linkages between human exploitation of landscapes, soil and vegetation change, and long-term climate change. The development of geoarchaeology has had a fundamental role in placing human activity in changing landscape settings by deciphering long-term trajectories of landscape change and by identifying the effects of human settlement on the sustainability of landscapes under human pressure. In Ethiopia, human activity as a factor of soil formation and development has rarely, if ever, been considered. Instead, an increasing number of studies, particularly pertinent to tropical environments, are showing how important the perception of local people is for addressing soil issues. In addition, recent archaeological survey has also indicated a greater time depth and gradual intensification of settlement development in the northern Aksum area over at least the last four millennia. As such, archaeology has moved beyond simple equations linking state formation, settlement expansion, agricultural intensification, and consequent deforestation, erosion, and soil degradation. Rather than raising new questions, these considerations refocus perspectives and viewpoints for old issues: Was intensification of agriculture a result of decreased land productivity, environmental/climatic worsening, increased population/market demands, or a combination of all of these?

Future Directions

Throughout the twentieth century, the understanding of the relationship between the development of subsistence systems and environmental changes at Aksum was based on a combination of multi-scale and multidisciplinary data. The interpolation of environmental data, which informs our wider research question of human settlement, was drawn from regional scale and context-specific archaeological records. The Aksumite urban development has long been linked to the idea of an agricultural substratum dependent on irrigation and responsible for land clearance. However, it is now clear that woods were not a common feature of the local landscape either before or during the Aksumite period and that agriculture relied on rainfall. Even if some aspects of ancient resource management have been investigated, site-specific studies and informed research are still very few. Furthermore, important issues such as terracing and field systems have yet to be addressed, albeit clearly priorities within the context of a changing landscape. A greater amount of environmental and archaeological records are needed particularly now that relevant comparable datasets have recently been acquired from elsewhere in Tigray (e.g., Gebru et al. 2009). The retrieval of landscape information is needed to contextualize non-environmental factors affecting societal decision-making over time. A greater amount of archaeological and historical data on the typology/typologies and distribution of rural settlements is necessary to address urban development and, subsequently, the decline of the Aksumite kingdom. The trajectories of settlement and land use diversification need to be addressed within their environmental and ecological contexts. Indeed, the paucity of buried landscape records implies that any attempt at modeling synchronous histories of forest expansion/clearance or the impact of changing rainfall, to mention just two important topics, has to rely on assumptions of environmental and cultural uniformity across vast regions.

Perhaps, the most compelling task currently facing archaeology and cognate disciplines concerns the development of multiple "applied approaches." In this respect, there are a number of opportunities and challenges for archaeological research at Aksum. The applied nature of archaeology has often been confined to the spheres of heritage creation and conservation, and tourism development. However, archaeology has much to offer to integrated, environmental research and can act as a bridge to link theories and methods from the humanities and earth sciences. Past societal responses to environmental stresses and opportunities were chosen from within a range of cultural and ecological constraints, and the understanding of these responses may well contribute to approaching and negotiating present and future environmental risks.

Akurgal, Ekrem

Ece Birçek
Istanbul, Turkey

Basic Biographical Information

Ekrem Akurgal was born on the family farm in the village of Haifa, near Tulkarem, Palestine, in 1911. At the age of two, his family returned to Turkey and he started his education at home. He graduated from Istanbul Males High School in 1932. As a requirement of the period of which the Turkish Republic was recently established, and due to new cultural and historical policies, he was sent to Germany as a scholarship student in 1932 and studied classical archaeology under Gerhart Rodenwaldt until 1940. In 1941 he was promoted to associate professor in Ankara University's Faculty of Languages, History and Geography and in 1949 became professor and professor emeritus in 1957. Akurgal served as the dean of the faculty from 1958 to 1959.

Major Accomplishments

Akurgal founded an archaeology library in the faculty that contains nearly 6000 books which are mostly published in foreign languages. This provides students and scholars with convenient access to an important reference resource. Akurgal excavated and revealed ancient sites such as Foça (Phokaia), Çandarlı (Pitane), and Çeşme – Ildırı (Erythrai) veBayraklı (old Smyrna). He has written numerous publications on ancient Greek, Hittite – Hatti, and ancient Anatolian civilizations in various languages. He was a member of seven academies in Europe and also an honorary member of many scientific institutions: the University of Bordeaux (1961), the University of Athens (1988), the University of Lecce (1990), and the Anatolian University (1990) where he was awarded the title of honorary doctor.

Ekrem Akurgal received the Order of Merit of the Federal Republic of Germany (1979), Goethe Medal (1979), Republic of Turkey Ministry of Culture Great Award (1981), Italian Commendatore Order (1987), and French Légion d'Honneur Officier (1990). He died in İzmir in 2002. His studies were continued by his wife, Meral Akurgal, who was an archaeologist and the closest assistant of Akurgal when he was alive.

Alberto, Carlos

Ramiro Javier March
CREAAH UMR 6566 du CNRS Centre de recherches en archéologie archéosciences et Histoire -INEE/SHS, Investigador del UMR 6566 CREAAH del CNRS, CNRS - Université de Rennes 1, Rennes, France

Basic Biographical Information

Carlos Alberto Aschero was born in Buenos Aires, Argentina, in 1946. His professional career began in the field of visual arts. In 1969, he graduated as art school teacher of drawing and, in 1972, as teacher of drawing and engraving. At the same time that he was studying visual arts, he began to study anthropological sciences at the University of Buenos Aires (UBA) where he graduated as Bachelor in Anthropological Sciences who specialized in prehistory and archaeology in 1974.

Between 1973 and 1975, Carlos Alberto Aschero began his career at CONICET (National Council of Scientific and Technical Research) as an initiation scholarship researcher. In April 1977, he began a career as a scientific researcher. He was an independent researcher between 1977 and 1996, and later he became senior researcher. As a CONICET researcher, Aschero was a member of the Advisory Commission on History, Anthropology and Geography for several periods between 2000 and 2012. He was the coordinator of the Commission between 2004 and 2007 and a member of CONICET Qualification Board between 2003 and 2004.

Carlos Alberto Aschero is currently Principal researcher at the ISES Institute of Social Studies, CONICET-National University of Tucumán (UNT). He was interim director between 2010 and Vice Director until 2016. He was representative of CONICET monitoring the Archeometry Laboratory Project (LALAR-INDyA, MINCyT-CONICET) and is currently the chairman of the board of directors of that organization, which was recently created in Argentina.

In 1971, Carlos Alberto Aschero began his teaching career while still a student at the National University of Tucumán, where he worked as associate professor. He was assistant professor between 1983 and 1993 of the Ergology and Technology Chair. From 1991, he was temporary Associate Professor of the Faculty of Natural Sciences of the National University of Tucumán and the Institute of Archaeology and Museum (IAM) until 1996. He was Director of the Institute of Archaeology, from 1995 to 1996, and Director of the IAM, between 1995 and 2002. In 2005, he became Full Professor of the Theory and Methods Chair in Archaeology of the Archaeology Department of the same faculty at UNT. From 2008, he reduced his full-time commitment to the post to part-time. He eventually became Honorary Director of the Institute from 2006 to 2010. He was also Professor of Field Practice III.

Carlos Aschero continued to work after his official retirement from CONICET in 2010. In 2018, he teaches about the rock art and hunter gatherers of Puna and Patagonia, within the International MASTER PREFALC in South American Prehistory Theory, Methodology and Practice of the University of Rennes 1 (France) and the National University of Trujillo (Perú). He was President of the Argentine Society of Anthropology between 1990 and 1993, and he is now an honorary member.

Major Accomplishments

In 1996 Carlos Alberto Aschero received the KONEX Award for the Humanities, and in 2001 he received the Bunge and Born Foundation award for his scientific career. He is a highly regarded archaeologist in South America. He is a specialist in diverse archaeological subjects and initially was part of the Argentine cultural historical school within C. Gradin's team. His first works reveal a strong influence from the French school, particularly of M. Brezillon, A. Leroi Gourhan, and F. Bordes (Aschero 1973).

Aschero worked on human productions derived from the concept of ergology in technofactures (both things or objects and symbolic

representations), developing various research programs on the lifestyles of hunter-gatherer groups and rock art in Argentina. His work on lithic typology (1983) has been a reference to Argentine archaeologists and has had international impact, which is remarkable, since it was never been published in a widely available medium.

Carlos Alberto Aschero's research on hunter-gatherer societies in the Southern Patagonian Andean area (Cuenca del Río paintings, Casa de Piedra Mount, Pueyrredón Lake, Santa Cruz Province) (Aschero and Aguerre 1979) and in the Northwest of Argentina (Puna Salada in Antofagasta de la Sierra, Inca Cave, Azul Pampa, Susques) (Aschero 2014) laid the foundations for a regional archaeology for those two regions of Argentina. In the same way, his research in these regions influenced the study of the process of American settlement (Aschero 2000), revealing the antiquity of human settlement in this part of the continent from very early dates.

His regional projects on rock art combined aspects in which symbolics were integrated into the vision, strategies, and social organization of these groups in relation to their natural environment (Aschero 2007). He also contributed to the historical reconstitution of different artistic styles, working on a diachronic reading of mural representations based on study of their production techniques, the reading of their structures and associations, and their relationship to the archaeological remains related to their manufacture. In his courses and publications, he delved deeper into the relationship between style and function, contributing to an enriched reading of these productions and to generating different readings of both the structures underlying those productions and the objects themselves, their manufacturing modalities and use.

In terms of his contributions to archaeological theory, Aschero developed an integrated view of archaeology in its social context and of its participation in the process of identity construction. Here, the influence of the postmodern school through Ian Hodder or Tim Ingold can be perceived. This is clearly seen in his recent works where humanism, ecology, and landscape are articulated as methods to explain cultural processes and hunter-gatherers' ways of living (Aschero 2010). His influence on Argentine archaeology is very important because he formed a school for his research as well as for training professionals (in the UBA as well as in the UNT). These scholars now occupy important position in the archaeology of the country. The range in their theoretical orientations reflects the intellectual freedom with Aschero encouraged during his career as an educator. The audiovisual production created by CONICET between 2014 and 2016, *Indigenous Technologies*, reflects Aschero's theoretical approaches and his multiple interests. It comprehensively conveys the breadth of his vision of archaeology, dealing with different aspects of Argentine archaeology from the settlement of the continent to the appearance of metallurgy. After he retired, he continued to work as archaeologist at Cueva Cacao 1 site at the Puna Catamarca province in Argentina. In 2018, human hair from his excavations was dated by the Centre for Isotope Studies at the University of Georgia to more than 40,000 BP (UGAMS # 33465, Sample ID M33-D5), opening up new debate concerning the peopling of South America.

Ali Kosh: Agriculture and Domestication

Frank Hole
Department of Anthropology, Yale University, New Haven, CT, USA

Introduction

Ali Kosh is a small mound on the Deh Luran plain of western Iran, close to the Iraqi border (32°33′26 18″ N and 47°19′30 11″ E). The site's prominence owes to its having revealed the first substantial evidence from charred plant remains of early stages of domestication in the Near East. Using the (at the time) new method of flotation, archaeologists recovered tens of thousands of seeds from Ali Kosh (Neolithic) and nearby Tepe Sabz (Chalcolithic), whose analysis by Hans Helbaek, a Danish paleobotanist (Helbaek 1969), showed an evolving competence in agriculture.

Key Issues

Excavated in 1961 and 1963 by Frank Hole and Kent Flannery, Ali Kosh is divided into three phases denoted by changes in plant and animal use, building types, burials, grinding stones, chipped lithics, and other artifacts (Hole et al. 1969; Hole 1977). The Bus Mordeh and Ali Kosh Phases are preceramic, while the Mohammad Jaffar Phase has some of the oldest ceramics in Iran. Radiocarbon dates show that the site was founded around 7500 cal. BCE and abandoned by 7000 cal. BCE (Zeder and Hesse 2000; Zeder 2000).

The Deh Luran plain, situated near the base of the Zagros Mountains had rich wild resources for the settlers to exploit and fertile soil in which to plant crops. The site was established near a marshy lake, which provided food resources, such as fish, water fowl, crabs, and turtles, as well as plants such as sea club rush whose seeds are edible. Local-hunted fauna included gazelle, onager, cattle, and pigs. The people also made extensive use of the wild-plant resources, including alfalfa, spiny milk vetch, *Trigonella* (a small plant of the pea family), various grasses, goosefoot, and fruit of the caper. While such plants were edible, because of their small seeds, they required considerable time to process. The people also imported and planted the larger-seeded emmer wheat and two-row hulled barley, neither native to the Deh Luran steppe. This basic picture of an important reliance on wild foods continued throughout the occupation of Ali Kosh, although their use diminished as domesticates increased, and the floral composition of the steppe gradually changed owing to cultivation, grazing by herds of

goats and sheep, and gradual burial of the marsh by geological processes.

Bus Mordeh Phase

Using red-clay slabs cut from the edge of the marsh, the first people at Ali Kosh built small rooms whose floors were covered with reed matting (Fig. 1). They planted emmer wheat and two-row hulled barley and kept a small herd of goats, but hunting and fishing provided a major part of their subsistence. It is probable that the people migrated into the mountains during the summers where cooler temperatures and fresh grass would be available for their herds. While they made thousands of small bladelets of flint, their inventory of grinding stones was limited. A small number of pieces of obsidian arrived from a source in Turkey, one indication of wide regional contacts. Although no burials were recovered, a number of beads and pendants made of boar tusk and shell are indications of personal decoration.

Ali Kosh Phase

A change in architecture is one of many differences with the Bus Mordeh Phase. By this time, red clay was no longer accessible, and walls were made of large slabs of clay cut directly from the land surface, and the houses were larger. Two such structures, with a narrow corridor between, lay next to an open courtyard with a brick-lined hearth. The courtyard was littered with stone tools for butchering animals, and the corridor between the buildings was filled with discarded bones (Fig. 2). In addition to using mats on the floor, they also made simple baskets, some of which may have been waterproofed with asphalt, taken from a seep near the site. Although there was no pottery, there were carefully made stone bowls and shallow trays of limestone, as well as clay figurines, mostly of goats and possibly humans, as well as other enigmatic clay objects. A copper bead hammered from a native source on the Iranian plateau attests to contacts, as does the increased amount of obsidian. This phase sees a proliferation of grinding stones in various new forms, implying a more sophisticated approach to the processing of wild plants and domestic crops.

There are burials beneath the houses, generally in small pits in which the bodies were tightly wrapped in matting and placed in a seated position. The skulls show annular cranial deformation,

Ali Kosh: Agriculture and Domestication, Fig. 1 Plan of Zone C2 (Bus Mordeh Phase). Small rooms of *red*-clay bricks and lithic workshop covered with the *ash* midden

Ali Kosh: Agriculture and Domestication, Fig. 2 Plan of Zone B2 (Ali Kosh Phase). Parts of two houses and courtyard, with lithic and faunal remains in situ

which elongates the skull. Numerous beads and other ornaments were on the bodies, some of which had been coated with red ochre.

Mohammad Jaffar Phase

The presence of pottery, lightly fired, chaff-tempered wares in three types – plain unpainted bowls, painted vessels, and red burnished bowls – denotes this phase and provides excellent stylistic links with other excavated sites in western Iran and Iraq, such as Sarab, Guran, and Jarmo.

The herds, consisting of both goats and sheep, show the characteristics of full domestication, and they now comprised the majority of faunal remains, although hunting of the large ungulates continued. The steppe vegetation now had *Prosopis*, a woody perennial with edible pods which, with fumaria and goose grass, are indications of grazing and cultivation. The filling of the marsh is attested by the absence of water-loving plants. In other words, human use and geological processes over the centuries had degraded the local environment.

Many of the flint, clay, and stone objects made in the Ali Kosh Phase continued in use, but a further innovation was the combination of shallow-basin grinding slab and mortar.

Together with grinding implements carried over from earlier times, there never had been as varied an array of artifacts to deal with the processing of cereals, which still were not "free-threshing."

Houses in the Mohammad Jaffar Phase showed further evolution. Now the walls had stone bases to control soil moisture, and the walls were of straw-tempered mud bricks (Fig. 3). Outside the houses are a number of burials lying in fetal position on their sides. Gone is cranial deformation, but a new array of ornaments occurs: bell-shaped pendants of marble, as well as labrets (one found in place), and beads of turquoise. Obsidian from eastern Turkey, seashells from the Gulf, specular hematite from Fars (southern Iran), and turquoise (possibly from northeastern Iran) are all evidence of widespread contacts through some means of exchange or transmission.

Ali Kosh: Agriculture and Domestication, Fig. 3 Plan of Zone A1 (Mohammad Jaffar Phase). To the *left*, a stone-founded wall of a house with tools and fauna. On the *right* are burials outside the structure

Because of its importance in the history of Deh Luran as well as to western Iran generally, the site has been designated as a protected reserve, off-limits to any non-archaeological activity.

Allen, Jim

Tim Murray
Faculty of Humanities and Social Sciences, La Trobe University, Melbourne, VIC, Australia

Basic Biographical Information

Frederick James (Jim) Allen was born in Gosford, NSW, Australia, in 1938. Graduating B.A. (Hons.) from Sydney University in 1965, Allen then undertook research for his doctorate in the Department of Prehistory at the Australian National University, being awarded the degree in 1969. From 1969 to 1972, he was a Lecturer in Prehistoric Archaeology in the Department of Anthropology at the University of Papua New Guinea. Following this, he took up an appointment as Research Fellow and then Fellow in the Department of Prehistory at the Australian University until 1985. During that time (in 1974), he was appointed Commonwealth Fellow, St John's College, Cambridge, UK. In 1985, he left the ANU to become foundation Professor of Archaeology at La Trobe University in Melbourne, Australia, retiring to become an Emeritus Professor in 1999. Allen's La Trobe years saw him take up Visiting Professorships in Auckland (1989) and Utah (1993). From 1993 to 1998, he was an Australian Research Council Senior Research Fellow. In retirement, he has also been a Member, Centre for Archaeological Research, Department of Archaeology and Natural History, Australian National University (1999–present), and a Research Professor, Department of Anthropology, University of Utah (2004–present).

Major Accomplishments

Allen has a unique position in the history of archaeology in Australia. Beginning at the University of Sydney with a training in Classical Archaeology, Allen moved to the Australian National University to undertake Ph.D. research on the historic site of Port Essington (1966–1969), completing the first ever dissertation on historical archaeology in Australia. Allen then moved to the University of Papua New Guinea (1969–1972) where he became a pioneer of prehistoric and protohistoric archaeology in that country.

Allen has contributed to a revolution in scientific knowledge about the prehistory of Melanesia and Tasmania. Returning to the Australian National University (1972–1984), Allen played a pivotal role in founding the field archaeology of

island Melanesia, through his leadership of the Lapita Homelands Project. In addition, Allen became involved in the prehistoric archaeology of Tasmania, which increased in intensity with his move to become foundation professor at La Trobe University (1985–1993), where he led the Southern Forests Archaeological Project. These major passages of fieldwork lay the groundwork for significant publications related to the archaeology of greater Australia. They also provided the framework for several major doctoral dissertations and other ancillary research. Allen has played a vital role in training several generations of Australian archaeologists and founded the Department of Archaeology at La Trobe University, Melbourne, in 1985.

Although he retired from academic archaeology in 1998, Allen has continued to conduct foundational research in Australian prehistoric archaeology and to draw together the threads of his diverse experience and knowledge of regional archaeology. Beginning with his work on developing models of prehistoric trade for egalitarian communities along the Papuan coast, which underscored the complexity of trade as a social act; then moving towards an exploration of colonization as a vector for increasing social complexity in Melanesia; and finally resting on a deep consideration of the prehistoric settlement of Australia and its consequences for the subsequent history of Aboriginal societies over the last 50,000 years, Allen continues to be vitally engaged in the research process. The importance of Allen's long connection with regional archaeology and its broader consequences was recognized by his election as Foreign Associate of the US National Academy of Sciences in 2012.

Allen, Mitchell

Megan Bailey
University of Maryland, College Park, College Park, MD, USA

Basic Biographical Information

Mitchell Allen is an archaeologist, publisher, and instructor. He obtained a Bachelor of Arts degree in Anthropology from the University of California, Santa Barbara; a Master's degree in Near East Studies from the University of Michigan; and, in 1997, a Ph.D. in Archaeology from the University of California, Los Angeles. His dissertation was concerned with Philistia, the Neo-Assyrians, and world systems theory (Allen 1997). Allen has taught at several universities in the United States, such as Mills College, the University of Maryland, Santa Clara University, and Diablo Valley College. Allen has taught and published on an eclectic mix of subjects, including the ancient Near East, archaeology, and scholarly publishing. The latter was borne out of 40 years of experience in the publishing industry. After retiring from Left Coast Press in 2015, Allen founded the Scholarly Roadside Service, a consulting company that specializes in academic publishing.

Major Accomplishments

Allen is best known for his career in publishing, during which he has overseen the publication of over 1500 books, journals, and software products. After working as an executive editor at Sage Publications, a social science publisher, Allen founded AltaMira Press in 1995 and directed its first 10 years. Under his supervision, AltaMira Press became a leading source of texts on cultural resource management, public history, and applied anthropology, among other topics. In 2005, Allen left AltaMira Press to establish Left Coast Press Inc., which he ran until it was sold to Routledge in 2015. There, he published books and journals in the humanities and social sciences, covering a broad range of topics such as anthropology, archaeology, sociology, ethnic studies, gender studies, heritage studies, public history, museum practice, qualitative research, and ethics. Allen's goal with both AltaMira Press and Left Coast Press was to create a space in which to produce progressive works (e.g., on indigenous and postcolonial archaeologies) and "find alternatives to traditional publishing" (Allen 2005). The latter can be demonstrated by the variety of unconventional textbooks Allen has published, including those that take the form of comic books and novels. Allen also encouraged the development of materials that would address gaps in scholarship, arguing that "our role is as much to shape scholarly output as to facilitate it" (Allen 2007a: 197). For example, at his urging, a textbook on archaeological ethics was written.

In addition to publishing the work of others, Allen has contributed several of his own publications, many of which are practical guides to navigating professional or academic life. He has advised on topics such as creative teaching methods (Allen 2007b), writing memorable and engaging works (Allen 2002), and the nature of

Allen, Mitchell, Fig. 1 Mitch Allen running a workshop on publishing. October, 2019, Flinders University, South Australia

academic publishing (Allen 2003; Allen and Joyce 2010).

In 2013, the World Archaeological Congress (WAC) gave Allen an International Achievement Award in recognition of his contributions to archaeological scholarship and publishing. Allen had collaborated with WAC to produce new publications such as the *WAC Research Handbooks in Archaeology*, the *Archaeology and Indigenous Peoples* series, and the journal *Archaeologies*.

Allen has returned to archaeology since retiring from publishing and is writing up a legacy project in which he participated, the Helmand Sistan Project, a joint US-Afghan survey and excavation expedition that worked in southwest Afghanistan from 1971–1979. He also conducts occasional workshops on writing and publishing in books and journals (Fig. 1). helping to build academic capacity and assisting universities to deal with the challenges of a changing world.

Alpaca and Llama: Domestication

Jessica L. Metcalf[1,2], Alan Cooper[2] and Jane C. Wheeler[3]
[1]Department of Chemistry and Biochemistry, University of Colorado, Boulder, CO, USA
[2]Australian Centre for Ancient DNA, University of Adelaide, Adelaide, SA, Australia
[3]CONOPA, Instituto de Investigación y Desarrollo de Camélidos Sudamericanos, Lima, Peru

Basic Species Information

Four camelid species inhabit South America today: the vicuña (*Vicugna vicugna*) and its domesticated form alpaca (*Vicugna pacos*), and the guanaco (*Lama guanicoe*) and its domesticated form the llama (*Lama glama*) (Kadwell et al. 2001). Since their initial contact with humans in the late Pleistocene and early Holocene, camelids have been an important resource for the South American people. Initially camelids were a primary source of food, which ultimately led to their domestication in the mid-Holocene. Over the last several thousand years, domesticated camelids have become important in many aspects of human life, from textiles to religious practices. In the sixteenth century, the Spanish conquest had a devastating impact on camelid populations. Tax records of herd sizes registered a 90% decrease during the first 100 years of Spanish occupation (Wheeler 2012). Therefore, we do not have a clear understanding of the diversity of alpaca and llama that existed under pre-conquest husbandry practices.

The vicuña is the smaller of the two wild camelids (35–50 kg), with very fine fiber (~12.5 μm) (Wheeler 1995; Mengoni Goñalons 2008). Alpaca closely resemble their wild vicuña ancestor, *V.v. mensalis*, but are slightly larger (adult weight 55–65 kg) with coarser, white to brown, and black fiber (~32 μm). Studies of pre-Spanish, alpaca mummies indicate that intensive selection for phenotype and high quality fiber production was practiced (Wheeler 2012). Two recognizably different varieties exist today, although they do not breed true. Alpacas with the "suri" phenotype have long dreadlock fibers, while those with the "huacaya" phenotype have a crimped fleece. They are also an important source of meat in South America.

Guanaco are larger (85–140 kg) and have coarser fiber (16.5–24 μm). Llamas are very similar in size and morphology to their wild guanaco ancestor, *L. g. cacsilensis*, although fleece color, texture, and fiber diameter have changed as a result of selective breeding (Mengoni Goñalons 2008; Wheeler 2012). Due to their robust nature, llamas have traditionally been used as pack animals, making possible the Inca expansion from southern Columbia to central Chile. However, they were also bred for fine fiber production prior to Incan times. These latter varieties have largely disappeared today, and although llama have several distinct fleece phenotypes, only the woolly (ccara), non-woolly (chaku), and dreadlock (suri) varieties are generally recognized.

Archaeological evidence tracking the timing and location(s) of camelid domestication in South America includes direct evidence (tooth morphology, osteometry, bone, and fiber morphology), indirect evidence (change in abundances and age groups), and contextual evidence (corral structures, art, and other cultural artifacts) (Mengoni Goñalons 2008). Archaeological evidence suggests that alpaca and llama were used

by the native people for a variety of purposes, including fiber for textiles, bones for tools, dung for fuel and fertilizer, pack animals for transportation of goods, and in religious ceremonies. Other evidence suggests that the high-elevation, montane Puna (grassland) region, which extends from central Peru, through Bolivia to northern Chile and northwestern Argentina, was the area in which the domestication of both camelids occurred (reviewed in Wheeler 2012 and Mengoni Goñalons 2008).

Alpaca were likely first domesticated in the humid Puna region of Peru during the early to mid-Holocene. Archaeozoological evidence, primarily based on tooth enamel patterns unique to alpaca, from Telarmachay rockshelter suggests that alpaca were domesticated prior to 6,000 years ago. Faunal remains from other sites suggest that alpaca were brought to lower elevation mountain valley areas ~3,800 years ago and into coastal sites in the last 1,000 years (Wheeler 2012). Similar to its ancestor vicuña, alpaca had a more restricted range than guanaco and llama. The historical distribution of alpaca included the Puna of Peru, Bolivia, and northern Chile, as well as the inter-Andean and coastal valleys of Peru (Mengoni Goñalons 2008).

Archaeozoological evidence indicates that llama were likely domesticated ~5,000–3,800 years ago at multiple locations in the Puna of the central Andes (northwest Argentina and northern Chile) and possibly in the high Andes of Peru (Wheeler 2012 and Mengoni Goñalons 2008). Beginning ~1,400 years ago, llama were brought into areas previously uninhabited by their wild ancestors such as Ecuador and southern Columbia. Generally, archaeologists have considered llama domestication independent, but more research is needed to fully understand the relationship between alpaca and llama domestication.

Both llama and alpaca figured prominently in the economy of the pre-Incan cultures, as well as the Incan empire (1470–1532 CE). At the site of El Yaral in southern Peru, naturally mummified alpacas and llamas from the Chribaya period (850–1470 CE) document both religious sacrifice of these animals and selective breeding for fine fiber production in both domestic forms (Wheeler 1995). Under the Inca, alpaca and llama production was strictly controlled by herding specialists and emphasis was placed on breeding animals for sacrifice to specific deities, for fiber production for the state-controlled textile industry, and as pack llamas for the army.

Although it is possible that the extant varieties (e.g., suri and huacaya alpacas, ccara, chaku, and suri llamas) are in fact relicts of highly selected Inca or pre-Inca varieties, the vast majority of alpacas and llamas reared in the Andes today are not the object of selective breeding practices. Genetic analyses of contemporary llama and alpaca populations have confirmed that extensive bidirectional hybridization has occurred (Stanley et al. 1994; Kadwell et al. 2001), possibly as a result of the breakdown of traditional breeding practices during the chaos of the Spanish conquest. Although guanaco and vicuña can produce fertile offspring when forced, there is no evidence that hybridization occurs in areas where their ranges naturally overlap. Only 6–20% of alpacas are free of llama ancestry, making the preservation of alpacas an urgent necessity.

Morphological and osteometric studies and DNA analysis have revealed that the domestication of South American camelids played out against a complex recent evolutionary history, potentially involving yet incompletely understood additional camelid taxa. Along with data from stable isotopes, these methods will be key to developing a better understanding of the timing and locations of domestication for both llama and alpaca, as well as the role of hybridization in preconquest breeds.

AlSayyad, Nezar

Nezar AlSayyad
College of Environmental Design, University of California, Berkeley, CA, USA

Basic Biographical Information

Dr. Nezar AlSayyad is an architect, planner, urban designer, and urban historian. He is a Professor of Architecture, Planning, and Urban History at the University of California at Berkeley where he currently serves as Chair of the University's Center for Middle Eastern Studies (CMES) and the Director of the International and Area Studies Graduate Program. AlSayyad holds a B.S. in Architectural Engineering and Diploma in Town Planning from Cairo University, an M.S. in Architecture from the Massachusetts Institute of Technology, and a Ph.D. in Architectural History from UC Berkeley.

Major Accomplishments

He is the recipient of many grants and awards for his research, books, films, and projects. In 1988, AlSayyad co-founded the International Association for the Study of Traditional Environments (IASTE). Today, he still serves as the Association's President and Editor of its highly acclaimed peer-reviewed journal *Traditional Dwellings and Settlements Review*. Professionally, AlSayyad has an active practice in the Middle East and the USA and is the Principal in XXA-Office of Xross-Cultural Architecture, an Architecture, Urban Design, and Planning firm with several award-winning credits. AlSayyad is the author, co-author, editor, or co-editor of many books. Additionally, he has written, co-produced, and co-directed two NEA-funded public television programs: "Virtual Cairo" and "At Home with Mother Earth."

A

Alta (Norway), Rock Art of

Jan Magne Gjerde
High North Department, Norwegian Institute for Cultural Heritage Research (NIKU), Tromsø, Norway

Introduction

The Alta rock art area is the largest concentration of Stone Age rock art in Northern Europe. This paper is a brief presentation of the rock art of Alta, Northern Norway. An overview of the sites with rock art in the Alta Fjord region can be found in Fig. 1. The find history of the rock art sets the historical background. Then the chronological framework for the rock art is presented, followed by a presentation of the rock art including the fascinating narrative hunting and fishing scenes and compositions where the interaction between rock art and natural features will be discussed. Some of the panels with rock art stand out as representations of miniature landscapes including references to landscape features such as lakes, rivers, and valleys where the rock art is deliberately placed in relation to these features.

Definition

The Alta rock art was discovered in 1973. It was inscribed on the UNESCO World Heritage list in 1985. New rock art is found every year adding to this large rock art record of the past. At present the Alta rock art area comprises numerous rock art sites with c. 6000 petroglyphs and five sites with rock paintings, in total about 100 figures. The rock art was made over 5000 years from about 5200 BC until about 0 AD. It is often referred to as hunters' rock art, also named northern tradition rock art of Scandinavia. Central to the rock art is large game; bear, elk, reindeer, but also halibut, seabirds, salmon, seals, and whales are depicted. Adding to this a large number of human representations are depicted in various activities. There are also boats and various artefacts such as bow and arrows and spears. The Alta rock art shows a unique narrative in scenes and compositions such as bear hunting, elk hunting, halibut fishing, reindeer hunting (see Fig. 2), sealing (see Fig. 3), and whaling. Some of the scenes cover more than 10 m of rock, where the figures and scenes are interacting in the storied rocks of the Stone Age. Returning to the same place for more than 5000 years makes Alta one of the nodes in prehistoric landscapes central to people inhabiting northern Norway and possibly beyond. Alta can be seen as a meeting place in the past central to people living in the area, likely used by inland and coastal groups (Fuglestvedt 2017; Gjerde 2010; Helskog 2014; Hood 1988).

Historical Background

The first rock art in Alta was discovered in 1926 by a Finnish ethnologist, Samuli Paulaharju, the rock paintings at Transfarelv (Transfarelvdalen) (see Fig. 4). However, it was not until 1966 that the archaeologists became aware of the rock paintings and documented them (Simonsen 1969). In the 1960s a small boulder with one human figure was discovered at Gjermunds by about 20 km from the main concentration of rock art later discovered at Hjemmeluft. It was named Isnestoften and later Isnestoften 1. Then in 1973 petroglyphs were discovered in Hjemmeluft at Ole Pedersen and at Storsteinen (Eng. the large boulder), defining Alta as a large rock art area. Since then rock art has continuously been discovered in Alta, the petroglyphs at Amtmannsnes in 1978, and the petroglyphs at

Alta (Norway), Rock Art of, Fig. 1 Map of the rock art in the Alta Fjord region. The sites with petroglyphs are marked in blue, while the paintings are marked in red. (Illustration by Jan Magne Gjerde)

Kåfjord in 1978. The second site with paintings at Transfarelv was found in the 1970s. Boulders with rock art at Isnestoften were discovered in 1998 and 2008 and paintings at Tollevik (Komsa) in 2000. Between 2002 and 2004, three new rock painting sites were found at Transfarelv. During the last years, five new sites have been found: petroglyphs at Svartskog 2016, rock paintings at the island Årøya (Årøya and Kongshus) in 2017 and 2018, and a boulder at Isnestoften in 2018. The rock art in Alta includes the five sites known by the World Heritage Listing, i.e., four sites with petroglyphs, Amtmannsnes, Hjemmeluft, Kåfjord, and Storsteinen, and the paintings at Transfarelv. Considering that several sites have been discovered in recent years, more rock art is

Alta (Norway), Rock Art of, Fig. 2 Narrative scene of a reindeer hunt with bow and arrow from the Bergbukten 4a panel at Hjemmeluft, Alta. The reindeer figure measures c. 10 cm. The panel is dated to c. 5000 BC–4000 BC. (Photo: Jan Magne Gjerde)

likely to be found in the Alta region in the future. An updated record of the Alta rock art can be found at the Alta Rock Art Archive at Alta Museum (www.altarockart.no/).

Key Issues/Current Debates/Future Directions/Examples

Dating of the Rock Art

A key issue to the dating of the Alta rock art is the notion that the rock art is made in the shore zone and that the land uplift has changed the elevation of the rock art in relation to the contemporary shoreline (Helskog 1983, 1999). The petroglyphs in Alta are located between 26.5 masl and 8.5 masl. The rock art at the same elevation holds the same or similar style in figures and selection of motifs (Helskog 2014). An example of this is the bear hunting scenes and the reindeer corrals that are all located between 22 masl and 26 masl. Another factor is that no scene or composition crosses the 2 m elevation. Even scenes of bears and bear tracks that can be followed for more than 8 m follow a horizontal orientation and do extend vertically the 2 m vertical limit. This also corresponds with the sea spray where the shore zone directly above the tidal zone is vegetation-free (from lichen and moss), hence making the figures more visible. The functional reasoning for placing the rock art in the shore zone has been further strengthened by Helskog (1999) in his study of rock art in relation to arctic hunter-gatherer cosmology where the rock art is placed in a three-tier cosmology in the middle world between the sky (upper world) and the sea (lower world). These factors as well as the extraordinary situation in Alta where the selection of motifs and composition follows the same elevation make shoreline dating a good method for dating the Alta rock art.

Alta (Norway), Rock Art of, Fig. 3 Narrative scene of a seal hunt at the Bergbukten 1 panel at Hjemmeluft, Alta. The boat figure measures c. 15 cm. The front of the seal figure where the head was is eroded. The panel is dated to c. 5000 BC–4000 BC. (Photo: Jan Magne Gjerde)

The studies by Helskog found the rock art to be made between 4200 BC and 0 AD (Helskog 1983, 1988, 2000). Excavations near the rock art area and a revision of the geological data made Gjerde suggest the initial rock art in Alta dates to c. 5200 BC (Gjerde 2010). This was later supported by Helskog (2012d, 2014) with minor modifications. This current record and dating shows rock art was made during a period of c. 5000 years between c. 5200 BC and 0 AD. A tentative chronological scheme of the rock art in Alta is found in Fig. 5.

Rock Art, Scenes, and Compositions

Between 26.5 masl and 22 masl, we find the earliest rock art in Alta, dated to between c. 5000 and 4000 BC. Some of these earliest panels with rock art in Alta are made up by several narrative scenes, and compositions stretching for more than 10 m in length include several hundred figures (see Fig. 6). The dominant motifs are large game with focus on elk and reindeer. The motifs include human representations, reindeer, elk, fish, bear, whale, seabirds, and geometrical patterns. What is prominent from the earliest rock art in Alta are the scenes and compositions depicting people in various activities, such as bear hunting, elk hunting, reindeer hunting (see Fig. 2), halibut fishing from boats, and what appears to be ritual activities (see Fig. 7). The boats have elk-head stems. The boats take part in various maritime hunting scenes, such as halibut fishing and sealing (Gjerde 2016). There are also many artefacts depicted as part of the activities, such as bow and arrows (see Fig. 2), spears, and elk-head staffs (see Fig. 7). The characteristic bear tracks are sometimes connected to bear dens where one at times can follow the bear tracks for about 8 m along the panel. We also see several reindeer enclosures and reindeer corrals, some of which hold drive fences guiding the reindeer (Helskog 2012a, b).

Alta (Norway), Rock Art of, Fig. 4 Section of the rock paintings at Transfarelv, Alta. One can see the human figure at the top, a reindeer, and a few geometrical figures. The human figure measures c. The panel is heavily eroded. The original photo to the left and DStretch color-enhanced photo to the right. (Photo and DStretch: Jan Magne Gjerde)

Between 21 masl and 17 masl, the rock art is dated to between c. 4000 BC and 3000 BC. The dominant motifs are still a large game with focus on elk and reindeer. In general, the motifs are similar to the earlier period. The seabirds are more frequent here, but there are still only a few figures. The large panels contain scenes and compositions such as bear hunting. The boats change in style, and the hull is more prominent, while the elk-head stem is still a feature. Some of the boats are involved in maritime hunting, such as sealing and possibly whaling small whales. The large narratives found in the earliest rock art are not that evident, and the large reindeer corrals and the numerous bear tracks are now missing from the record.

Between 16 masl and 14 masl, the rock art is dated to between c. 3000 BC and 2000 BC. We now see a change in the motifs. Most notable are the large human representations and the large animals (see Fig. 8). No boats have yet been documented from this period. Another notable feature is that it is not as easy to distinguish the species of some of the deer figures (elk or reindeer). While the rock art from between 5000 BC and 3000 BC included humans depicted in activities, the narrative scenes are no longer found in the record.

Between 13 masl and 10 masl, the rock art is dated to c. 2000 BC until c. 1000 BC. In this period, less rock art is made in Alta. The most notable change from the previous period is that the elk is missing from the record. The boats have a different style than the earlier boats from Alta. Boats of this period have been compared to the South Scandinavian Bronze Age boats and show similar traits (Gjerde 2017; Helskog 2012c; Kaul 2012). Another stylistic feature is the large "oversized" antlers of the reindeer. One of the scenes shows what is likely to be two human figures in a sword fight with swords and shields, similar to

Alta (Norway), Rock Art of, Fig. 5 Chronological scheme of rock art in Alta. (With kind permission from Karin Tansem)

Alta (Norway), Rock Art of, Fig. 6 Section of the Bergbukten 1 panel at Hjemmeluft, Alta. The panel is dated to c. 5000 BC–4000 BC. The photo covers c. 8.5 m of the panel. The panel holds c. 300 figures. (Photos and photo compilation: Jan Magne Gjerde)

Alta (Norway), Rock Art of, Fig. 7 Section of the Ole Pedersen 9 panel. Central are the male persons with what appears to be headdresses and holding elk-head sticks interpreted as "shamanic" paraphernalia. The central human figures measure c. 30 cm. (Photo: Jan Magne Gjerde)

the "warrior scenes" in South Scandinavian Bronze Age rock art (e.g., Toreld 2015).

Between 10 masl and 8 masl, the rock art is dated to c. 1000 BC until c. 0 BC/AD. This period reflects the previous period, and only a few figures are found, including one elk, but no reindeer figures. We find several boat depictions comparable to the South Scandinavian Bronze Age and Iron Age boats (Gjerde 2017; Helskog 2012c; Kaul 2012) (see Fig. 9).

Natural Elements and Landscapes of Rock Art

The sites in Alta are some of the best examples of interaction between rock art and natural elements, the art and the canvas. This is especially true for the earliest rock art dated to between c. 5000 BC and 3000 BC. Some of the panels seem to be miniature landscapes where the figures are placed in relation to the topography of the rock, pools, cracks (see Figs. 6 and 10), and discoloration or other features in the rock. These natural elements may represent valleys, rivers, or lakes, and the rock art figures appear to interact with these features (Gjerde 2010; Helskog 2004; Helskog and Høgtun 2004). Bergbukten 1 at Hjemmeluft (see Figs. 6 and 10) contains more than 300 figures and is dated to c. 5000 BC–4000 BC. This panel holds several clues to seasons in rock art, such as the autumn reindeer corral and the bear dens and spring bear hunting (Helskog 2012b). Hence, it has been interpreted as a "panel of the year," representing seasonal activities (Helskog 1999, 2004). On some panels, the rock art interacts with the canvas or the natural features of the rock. At the Ole Pedersen 11A panel in Hjemmeluft, dated to c. 4000 BC–3000 BC, the canvas of the rock appears to be a representation of the aurora borealis, the northern lights (Tansem and Johansen 2008). The figures appear to interact with the natural elements taking part in the storied rocks (see Fig. 11).

Alta (Norway), Rock Art of, Fig. 8 Section of the large Amtmannsnes 2B panel. The panel holds large human figures. The central figure measures c. 85 cm. (Photo: Jan Magne Gjerde)

Alta (Norway), Rock Art of, Fig. 9 Boat representation at Apana Gård 12. The boat measures c. 1.10 m. (Night photo: Jan Magne Gjerde)

Alta (Norway), Rock Art of, Fig. 10 The "miniature landscape" at Bergbukten 1. Compare with Fig. 3 where one can see part of the reindeer corral at the left of this photo and the bear hunting scene. Here it is apparent how the figures relate to the natural elements such as miniature lakes, rivers, and valleys in the rock. (Photo: Jan Magne Gjerde)

Alta (Norway), Rock Art of, Fig. 11 The aurora borealis in the rock at Ole Pedersen 11A. Note how the figures interact with the rock surface in "black and green" bands similar to the northern lights. (Photo: Jan Magne Gjerde)

The rock art is related to the natural elements of the rock so that the panels appear to be miniature landscapes. In some cases, the rock art may also signify the place of the activity, such as the bear dens, the halibut fishing from boat, and the shore zone represented by people in boats driving reindeer onto the shore where a hunter is waiting for them. These may be clues to the physical landscape, geographical references included in the rock art (Gjerde 2010). Some rock art panels may represent "maps" including information on activities, seasonality, and places in the landscape.

Future Directions

The Alta region holds numerous Stone Age settlements. Within the same area, there are also Stone Age quarries. Few attempts have been made to integrate the rock art into the rest of the prehistoric remains in the Alta Fjord region. The main future direction is to see how the rock art relates to the settlements and other cultural remains in the area. An ongoing research project is currently focusing on these topics.

Altai: Paleolithic

Nicolas Zwyns
TRACES, Université Toulouse Le Mirail, Toulouse, France
Department of Human Evolution, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany

Introduction

The Altai range is located at the cross-roads between Central and Northeast Asia, between 49–52°N latitude and 32–88°E longitude. The Altai plain borders it in the north and the Ob River Basin opens to the west on the Siberian plain. On the northwest border stand the Salair and the Alatau ranges and in the southwest, the western Sayan range. In the south, the Mongolian Altai runs east to the Gobi Desert and joins the Kazakh steppe to the west. In the southwest, the Altai is separated from the Central Tian Shan by the plains of the eastern Balkash, by the Tarbaghatay range, and by the surrounding Zaisan. The plains reach the Xinjang and the Taklamakan desert via the Turpan-Ami depression and southern and Inner-Mongolia via the western edge of the Gobi desert.

The Altai Mountains are the result of a complex and contrasted history. Several periods of complete flattening (e.g., Early Mesozoic, Late Paleozoic) of the landscape have been recorded and the current setting was initiated during the Late Jurassic (Chlachula 2001). The Siberian Mountains are seen as the continuity of uplifting processes starting from the Baikal region, progressing from east to west and reaching the Altai-Sayan during the late Pliocene.

The Altai alpine ridges, such as the Chuya, Saylugem, Katun, and Kuray, include peaks with a maximum elevation of 4,506 m asl. The high plateaus of more than 2,000 m in elevation (e.g., Ukok, Chulyshman, Ulugan) represent a third of the Altai territory and intermediate mountain landscapes, ranging between 800 and 2,000 m asl, account for about half of it. These are mainly located in the northern and western regions and their relief is shaped by active hydrographic networks and by selective erosion. Intermediate mountain landscapes were formed by the erosion of the peneplains of large plateaus (Shahgedanova 2003). Two main lakes, the Markakol and the Teletskoe, are located respectively at the southern and northern edges of the Altai range. The current climate is continental with contrasting seasonal climatic inversions. The winters are generally cold with mean temperatures ranging from −16 °C in the foothills to −36 °C in the high mountains (Shahgedanova 2003). The minimum temperature is recorded in the Chuya depression, reaching −60 °C. Precipitation is stronger in the northwestern part of the Altai, as the southeast is more arid (Chlachula 2001).

The earliest sedimentary deposits in the Anuy river valley were first attributed to the last interglacial, c. 120–110 ka, when karsts were formed due to the exposure of carboniferous formations (Baryshnikov and Maloletko 1997). Such a chronological attribution is consistent with the tectonic activity recorded at the end of the Middle Pleistocene that would be responsible for a deepening of the valley system by about 100 m the Anuy River and about 200 m in the Katun River. This view, however, has been challenged on the basis of radio-thermoluminescence (RTL) measurements providing ages of c. 225 ka for the pebble and gravel layers at the base of the Anuy alluvial plain (Derevianko et al. 2003).

During the first half of the twentieth century, the interest for Paleolithic research in the Altai was stimulated by the collection of surface artifacts at the confluence of the Katun and the Biya rivers and with excavations in the Byisk area. In 1954, S.I. Rudenko reported evidence of Paleolithic occupation at Ust-Kanskaya Cave, along the Charysh River. Rudenko quickly noted some Mousterian typological features on the lithic assemblage, and eventually attributed the human occupation to the Last Glacial based on the fauna recovered. A.P. Okladnikov recognized affinities with the Mousterian from Western Europe and Central Asia and until the discovery of Ulalinka site in 1961, Ust-Kanskaya was considered the most ancient Paleolithic site in the Altai. Okladnikov discovered and excavated important

sites in the region, such as Strashnaya Cave, Denisova Cave, and Kara-Bom and remains a major figure in Altai Paleolithic archaeology. His work in Uzbekistan, the Baikal area, Mongolia, and the Far-East led him to consider the existence of a vast Sibero-Mongolian Levallois techno-complex (Fig. 1).

Among his students, A.P. Derevianko appears as the most influential contributor to Paleolithic research in the Altai region. He participated in the discovery of the Anuy I open-air site in 1983 and Okladnikov Cave in 1984. At about the same time, excavations started at Maloyalomanskaya Cave, in the Katun basin. Derevianko discovered the site of Ust-Karakol 1 at the confluence of the Karakol and Anuy Rivers. The latter was first excavated in 1986 (sector 1) and excavations at the nearby site of Anuy II started in 1989. Since the beginning of the 1990s, the sites of Karama, Anuy III, and more recently, the Mousterian site of Chagyrskaya were discovered and his team. Following Okladnikov's legacy, Derevianko undertook numerous international expeditions (e.g., Montenegro, Uzbekistan, Mongolia, Far-East) and developed many collaborations. This approach generated a rich data set upon which synthetic models of population dynamics could be built (Derevianko 2011) (Fig. 2).

Paleolithic sites are mostly located in the north-western and in the central part of Gorny-Altai, between the Alpine relief and the northern plain. They lie in intermediate mountain zones, generally between 300 and 1,200 m asl. In the north-west, Strashnaya Cave and Chagirskaya Cave are located in the Charysh Basin. Okladnikov Cave, Isrkra Cave, Karama, Anuy I-III, Denisova Cave, Ust-Karakol, and Kamminaya Cave are located in the Anuy basin and Ust-Kanskaya is located further south along the Charysh, in the Central Altai. Ulalinka was found near the city of Gorno-Altaisk, and the Biyka Cave complex and the site of Kara-Tenesh lie upstream along the Katun River. The Tiumechin complex and the Kara-Bom site are located near the Ursul river, and Maloyalomanskaya Cave can be found along the Mala Yaloman, a small tributary of the Katun. Only a few sites such as Barbughazy, Torgun, and Yustid are found in the southeast, and they are mainly attributed to the final stages of the Paleolithic.

Definition

Based on the Eurasian system of division, three main periods can be recognized during the Paleolithic of the Altai: the Lower, Middle, and Upper

Paleolithic. The Lower Paleolithic corresponds to the first human occupation of the Altai that would start c. 800 ka. The Middle Paleolithic would start sometime at the end of the Middle Pleistocene and last until c. 50 ka. The Upper Paleolithic covers a time range from c. 50 ka to the end of the Pleistocene.

Key Issues/Current Debates

The Lower Paleolithic

According to Derevianko (2011), the Altai was first colonized by small populations of *Homo erectus*/*ergaster* starting from c. 800 ka, that subsequently disappeared from the region c. 500 ka.

The site that would best represent this first wave of human occupation is Karama, along the Anuy River (Derevianko and Shunkov 2009). The diversity of the exotic flora is said to fit with a Middle Pleistocene attribution and the RTL dates of 643 ± 130 ka and 542 ± 110 ka have been obtained on the lower portion of the sequence (layers 8–14). Although the identifiable artifacts do not include handaxes, Derevianko and Shunkov tend to emphasize elements that would fit with an Acheulean attribution. The technology is described as cores on pebble blanks and flakes with subparallel dorsal pattern. The tool-kit includes various kinds of scrapers (including naturally backed examples), Clactonian notches, and choppers. More surprising is the reported presence of core-like endscrapers with abrupt retouch. Derevianko acknowledged that the first Lower Paleolithic occupation of the Altai is elusive and likely represents a short-term event. Discovered in 1961, the site of Ulalinka was originally presented by Okladnikov as evidence of Lower Paleolithic human occupation. The chronological attribution beyond the Bruhnes-Matuyama reversal and the authenticity of the lithic artifacts became, however, quickly controversial. The period following the initial peopling of the Altai corresponds to a gap in the archaeological record followed by what is interpreted as a replacement of population (Derevianko 2011). Based on assemblages from the lowermost layers in the Denisova Cave main chamber, Derevianko suggested that a new population settled in the Altai during the Middle Pleistocene, around 300 ka (Fig. 3).

These newcomers bring the first evidence of Levallois and blade technology. Although first mentioned as Mousterian, the archaeological material is also seen as derived from a Late Acheuleo-Yabrudian (Derevianko and Postnov 2004).

The attribution of these assemblages to the Lower Paleolithic is mostly based on RTL dates. At one standard deviation, ages between 330 and 130 ka were obtained on the layer 22. Two inversions of magnetic polarity have been recorded and, following the dating of the layer, interpreted as Biwa I (220–176 ka) and Biwa II (330–266 ka). This contradicts estimations based on tectonic, geomorphology, and small mammals that suggest a formation of the karstic system too closer to the last Interglacial. Furthermore, some authors have warned that the RTL method follows different assumptions than the standard TL and that unbleached particles in cave sediments may be problematic for luminescence dating. In front of the cave, the lower part of the sequence is attributed to the last interglacial and the single magnetic inversion recorded is currently assigned to the Blake episode.

Altai: Paleolithic, Fig. 3 Denisova Cave. (Picture by N. Zwyns)

The Middle Paleolithic

The Altai Middle Paleolithic is described as belonging to two main variants. Based on Levallois indexes and on frequencies of Mousterian elements, Shunkov (2005) recognizes a Mousterian variant opposed to a Levallois-Mousterian variant. This variability was

interpreted as reflecting different settlement patterns of a single MP tradition. Mousterian assemblages, which are only represented in cave sites, would represent long-term occupations. On the contrary, the Levallois-Mousterian seasonal occupations are associated with open-air contexts. A behavioral ecology approach was further developed by P. Wrinn (2010). Based on the occurrence/absence of formal tools or chips that would testify to tool rejuvenation or raw material management, he classifies MP occupations into three main categories: ephemeral/task specific, ephemeral generalized, and intermittent generalized occupation. His analysis of the fauna and of the lithic frequencies suggests a low intensity of human occupation in the region. The Altai is then seen as a refugium for hominins during cold phases.

The *Levallois-Mousterian variant* is mainly represented by the assemblages from the middle part of the section at Denisova Cave (layers 20–12), the lower and middle part of the sequence at Ust-Karakol I sector 1 (layers 19–12), and the lowermost cultural layers at Kara-Bom. In addition, the variant possibly occurs at Ust-Kanskaya and Strashnaya Cave. Kara-Bom and Ust-Karakol assemblages show a technology characterized by the production of Levallois points from tabular cores. The reduction is mostly unidirectional but also includes bidirectional instances, with occasional removals of debordant blanks to reshape the convexities of the core. The reduction system includes the production of elongated spalls. Although it should be supported by additional chronometric data, the Levallois-Mousterian would appear during the OIS5e, c. 120 ka and eventually disappear from the region at the beginning of OIS3.

The *Mousterian variant* is defined based on the material from Okladnikov and Chagirsakaya Cave. Recently, Derevianko and Markin suggested that these two sites illustrate the existence of a distinct MP facies, relatively late, and intrusive, which they call the Sibiryachikha variant (Derevianko and Markin 2011). It is characterized by a lack of Levallois elements and by a good representation of Mousterian retouched tools, such as various types of sidescrapers and notches. These assemblages seemingly appear at the beginning of OIS3, around 55–50 ka, and last at least until the middle part of OIS3, c. 37 ka. The Sibiryachikha assemblages are said to represent Neandertal populations moving across Central Asia (e.g., Teshik-Tash) and subsequently penetrating in the Altai under the demographic pressure of the spreading Modern Human populations.

In sum, two variants can be distinguished among the MP assemblages from the Altai. The Levallois-Mousterian is better represented in the archaeological record and seems to predate the appearance of a more elusive, and apparently intrusive Mousterian. How much seasonal, functional, or cultural factors are responsible for such variability is not yet clear.

The Upper Paleolithic

The local Levallois-Mousterian is said to have gradually evolved into two main UP variants, the Ust-Karakol and the Kara-Bom variants. Derevianko (2011) sees both UP trends as the result of an incipient evolution from a local Middle Paleolithic background. In his model, the latter process is used to support a scenario of multiregional emergence of modern human anatomical and behavioral features. Other authors have underlined the role of site-formation processes to explain the apparent transitional character of some assemblages or the regional discontinuity of human occupation (Wrinn 2010; Zwyns 2012). Following these views, the Altai data set may support to models in which population movements more consistent with the Out-of-Africa hypothesis.

The Kara-Bom variant (or *Initial Upper Paleolithic*) is defined on the basis of levels OH5 and OH6 from the eponymous site, but is also described at Ust-Karakol 1 (sector 1, OH5.5 and OH5.4), Kara-Tenesh, Maloyalomanskaya Cave, and in the Byike complex. The defining technological features are clearly expressed in the production of laminar blanks (Fig. 4).

Altai: Paleolithic, Fig. 4 Initial Upper Paleolithic (the Kara-Bom variant) from Ust-Karakol 1 sector 1. 1, 2, blade with inverse proximal retouch; 3, bidirectional blade core; 4, burin-core. (Drawings by N. Zwyns)

Asymmetrical blade cores were reduced from two opposed platforms. The main flaking surface is usually located on the broad face of the core and one of the narrow faces is used to reshape lateral convexities. Large and robust blade blanks are produced and retouched whereas thick technical side blades were turned into burin-cores to detach small laminar blanks (Zwyns et al. 2012). This technology is seemingly associated with an early appearance of ornaments, starting from c. 42 ka. The Kara-Bom trend has been considered as an example of local and gradual transformation of the technology observed in the underlying Middle Paleolithic layers (Derevianko 2011).

The *Ust-Karakol variant* (or *Early Upper Paleolithic*) first occurs during the middle phase of OIS3. It is marked by the production of small laminar blanks from narrow-fronted and carinated cores reduced by direct percussion. It is associated with the generalization of bone tools and fully developed forms of ornaments. The defining assemblages are Ust-Karakol 1 (sector 2) layers 11–8, but other assemblages from Anuy I-III, Strashnaya upper levels, Tyumechin-4, and Ushlep 6 are considered analogous. It is said to have evolved from a Levallois background assigned to OIS5e at Ust-Karakol 1, sector 2, (layers 19–18). Originally described as non-

Altai: Paleolithic, Fig. 5 Main models of Upper Paleolithic emergence in the Altai: summary (see text for references)

Levallois, the central chamber of Denisova Cave was later said to illustrate the same gradual development, between 100 and 30 ka, toward genuine UP (layers 11 and 9). Although the Ust-Karakol trend is sometimes listed as a possible source for the spread of microblade technology in Northeast Asia, the early UP assemblages display no clear evidence supporting an early use of pressure flaking.

A recent study based of the laminar technology of Kara-Bom and Ust-Karakol variant supports the existence of two main technical traditions at the beginning of the Upper Paleolithic (Zwyns 2012). By comparison with Europe and the Levant, the Kara-Bom variant is assigned to the Initial Upper Paleolithic (IUP) to describe the presence of derived UP features without necessarily implying a local transition. The IUP definition reinforces analogies proposed by numerous authors (e.g., Derevianko 2011) with sites from the Cis-Baikal (e.g., Makarovo-4), Trans-Baikal (e.g., Tolbaga, Barun-Alan, Khotyk, Kamenka A and C, Varvarina Gora, Podzvonkaya), or Mongolia (Tolbor 4). The IUP is followed by an Early Upper Paleolithic (EUP) phase with a shift toward developed UP features (Ust-Karakol variant). The latter correspond to a series of behavioral changes in terms of economy (emancipation of the bladelet production) knapping techniques (shift to soft hammer), but also probably in terms of weaponry (composite spears). Although they are poorly dated, the two phases appear separated by a significant time span and by climatic events such as Heinrich 4 (Fig. 5).

According to the chronometric data, the Upper layers of Anui 2 document human presence during a time span that covers the end of OIS3 until the Late Glacial Maximum. It is not yet clear if human groups inhabited the lower valley of the Altai during the LGM or if the record illustrates a regional discontinuity in human occupation. It seems, however, that the occupational hiatus is more clearly marked than in the piedmonts. Starting from OIS 2, the blockage of river systems driven by the expansion of mountain glaciers led to the multiplication of lakes. Eventually, periodic drainage

events may have caused catastrophic floods that may represent a source of bias in the archaeological record for the period between 26 and 13 ka.

Human Remains

At Okladnikov Cave, dental remains occur in stratum 2 with a left lower molar, but also in stratum 3 with a left lower premolar, a left lower molar, and a right lower molar. Postcranial remains are found in stratum 2 with an adult humerus, and in stratum 3 with a subadult humerus and a hand phalanx. The good preservation of the collagen extracted from the phalanx, from the subadult humerus, the femur, and from the adult humerus has led to the reconstruction of the mtDNA sequence which has been identified as Neandertal (Krause et al. 2007). The archaeological assemblage is Mousterian but the dating of the human occupation is far from clear. Direct dates would indicate that the Neandertal presence in the area lasted until at least 37 ka 14C BP.

At Strashnaya Cave, eight deciduous teeth presumably belonging to a single individual come from an unclear stratigraphic context that can be attributed to the UP. The specimens could not be assigned to a clear taxon. At Maloyalomanskaya Cave, the discovery of a single human tooth has been reported, but no detailed description has been published.

At Denisova Cave, two teeth have been found in the 1984 collection from the central chamber. Denisova 1 is an upper central incisor found in layer 12. Although it has been previously published as a human tooth, Viola et al. (2011) assign it to a worn incisor from a large bovid. Denisova 2 is a deciduous molar (right first lower) found in layer 22.1 that would date to at least OIS 5e. In 2000, layer 11.1 of the south gallery yielded a tooth belonging to a young adult and identified as a third or second upper molar (Viola et al. 2011). Denisova 3 is the proximal epiphysis of a juvenile manual phalanx uncovered in layer 11.2 of square D2 of the east gallery. The phalanx belongs to a distinct individual with an age evaluated at around 6–7 years old. Both mtDNA and nuclear DNA were extracted from these remains, resulting in the identification of a hitherto unknown archaic hominin (Krause et al. 2010; Reich et al. 2010). The nuclear DNA indicates that these hominins, referred to as "Denisovans," belong to a lineage sharing a common origin with Neandertals that post-dates the split with MH ancestors. Initial morphological descriptions of the tooth noted a set of archaic features not seen in Neandertals or in early modern humans, further suggesting a distinct evolutionary history.

At the recently discovered Chagysrkaya Cave, Viola et al. (2011) described human fossils associated with layers 6b and 6c. Chargyrskaya 1 is a worn upper deciduous canine and Chagyrskaya 2 is an atlas fragment. Both fossils are associated with layer 6b. Chagyrskaya 3 is an upper premolar and Chagyrskaya 4 is a lower incisor. Both are worn and small and would fall outside the range of Neandertals. Nevertheless, the mtDNA is under reconstruction; although the results are not fully published, they seem to indicate an attribution to Neandertals (Viola et al. 2011). The rich lithic and fauna assemblage is assigned to the Mousterian and the excavation is still ongoing.

Future Directions

The recent identification of the Denisovans in the Altai opens up new perspectives for understanding the peopling of Asia. Genetic data suggest that, apart from some present-day populations from Melanesia and Australia, Denisovans did not contribute significantly to the genome of Eurasian populations (Reich et al. 2011). The current geographical distribution of the Denisovan genetic input lead to the hypothesis that the Altai might represent the northern edge of their territorial expansion. Where and when they did interbreed with MHs is still unclear and the current data do not rule out other sterile encounters.

The human fossils from Denisova Cave have not been directly dated. New radiocarbon dates

were produced on cut-marked bones and bone tools that belong to the same layers as the Denisovan fossils. The results indicate post-depositional admixtures from subsequent and underlying layers (Reich et al. 2010). The chronological and cultural attributions of the Denisova hominins remain, therefore, uncertain. Although it shows the first occurrence of modern behaviors, the IUP assemblages predate the earliest known MH fossil from Siberia. According to the data at hand, the latter appears contemporaneous of the EUP. The Altai Neandertals are, up to now, the only taxon clearly associated with an archaeologically defined unit, namely, the MP of Mousterian variant. The makers of the Levallois-Mousterian variant are still unknown and the identity the IUP populations is yet to be found.

Finally, the apparent complexity of the Altai Paleolithic human occupation likely reflects a lack of reliable and comparable chronological data. Recent steps taken toward the identification of human remains in clear archaeological, taphonomic, environmental, and chronological contexts have already proven to be highly valuable. Further efforts to acquire high-resolution datasets are, nevertheless, essential in order to test current models. There is a few doubt that it will provide new keys for the understanding of the peopling dynamics in a region that stands as a gate between Central and Northeast Asia.

Altamira and Paleolithic Cave Art of Northern Spain

Diego Garate
Arkeologi Museoa, Archaeological Museum of Biscay, Bilbao, Spain

Introduction

There are more than 120 caves in the Cantabrian side of Northern Spain that preserve rock art produced during the Paleolithic. In 1985, one of them, Altamira, was declared World Heritage as it represents "a masterpiece of human creative genius" (Criterion I & III: http://whc.unesco.org/en/criteria/). In 2008, this same recognition was extended to another 17 caves in the region.

Some of the archaeological sites with Cantabrian Paleolithic cave art have also produced outstanding portable art pieces on bone, antler, or stone (Corchón 1986; Barandiaran 1989).

Definition

Cave art of Northern Spain extends along a 400-km coastal zone, from the Bidasoa's to the Nalón's river basin, coinciding with the distribution of the karstic lithology of the Cantabrian coast. Especially noteworthy are the concentrations associated with the mouth of the Sella and the Saja-Besaya river basins; the Nalón, the Pas, and the Asón middle basins; or the coastal areas of Llanes and Castro Urdiales (González Echegaray and González Sainz 1994).

This area is one of the classic regions of Paleolithic cave art (Balbín Behrmann 2004), together with the Pyrenees and the Dordogne, and other emerging regions such as Andalusia and Ardèche. New sites continue to be discovered, increasing the number of sites and gradually redefining the characteristics of this artistic tradition.

Altamira was not just the first recognized decorated cave, but one of the most outstanding because of its artistic quality and the quantity of motifs preserved. The cave was discovered in 1879 by the daughter of Marcelino Sanz de Sautuola who for years had studied the cave. The discovery generated a huge controversy about the finding's authenticity, which was only resolved in 1902, when the existence of Paleolithic art was accepted by the broader scientific community (Moro Abadía and González Morales 2004). The turn of the century brought the first systematic surveys that resulted in the discovery of other new and spectacular decorated caves (Alcalde del Rio et al. 1911) (Fig. 1).

After one and a half centuries of research, the wide variability and the specific features of each site are now well known (González Sainz 2004). Each of these is unique, and we have identified a number of graphic devices that were continuously reused throughout the Upper Paleolithic with art assemblages involving hundreds of figures such as Peña Candamo, Llonín, Tito Bustillo, Altamira, Castillo, or La Garma. Others, however, were only decorated at specific points in time but, in some cases, also in a very profuse manner (e.g., Ekain

Altamira and Paleolithic Cave Art of Northern Spain, Fig. 1 Distribution map of decorated caves on the Cantabrian coast of the Iberian Peninsula (D. Garate)

or Altxerri). In some cases (such as in Cullalvera), the artists penetrated the farthest depths inside the caves for their activities. But quite often (such as in La Lluera, Chufín, or Venta Laperra), the decorated panels are located near the entrances, even illuminated by natural light.

Most of the others have very modest assemblages with only a few images represented. This

Altamira and Paleolithic Cave Art of Northern Spain, Fig. 3 Main panel of Tito Bustillo cave (R. de Balbin)

suggests that the artistic production was not probably the main activity practiced at these sites (Fig. 2).

Figurative subject matters are dominated by animals. From the beginning are horses, bison, aurochs, and goats, but during later periods, the horse and the bison dominate the iconography as is found in other regions (Pyrenees and Dordogne). The animals appear together with specific geometric signs such as rectangles divided internally, rectilinear forms with central bulges, and simpler shapes such as cupules in rows or clouds of dots. Although there are a few human figures, there are representations of vulvas and hands stencils are abundant.

The techniques used by the artists are basically painting and engraving. The color palette was limited: different hues of black, yellow, and red. The first was obtained from charcoal, burned bones, or manganese oxides, while the others were produced using different sorts of iron oxides. The color was applied directly as a crayon or as a processed paint. The application of the pigment with the fingers to produce dotted animals is a technical peculiarity specific to this region. Engravings made with flint tools or with the fingers on soft surfaces had different depths and were produced by one or repetitive strokes. In this case, multiple striping to indicate animal fur, especially on deer, is also specific to the region (Fig. 3).

Key Issues/Current Debates/Future Directions/Examples

Paleolithic art research presents a number of common problems in the various regions where it appears. It is difficult to interpret its original meaning, and the establishment of chronological sequences has been a priority, given the difficulties of directly dating the art. Even though the message originally transmitted by the Paleolithic images cannot be recovered, through their study we can explore the lifestyle and the way the artists understood the world and, by extension, to the societies that created them (Fig. 4).

Chronological Distribution

The improvement of radiocarbon and other dating techniques has demonstrated that a highly developed art form existed from the beginning of the Upper Paleolithic.

The chronology of art production in caves along the Cantabrian coast requires further research. Radiocarbon dates remain controversial (Fortea Perez 2000–2001), and other techniques such as calcite formations dating, under or superimposed over the figures, provide a lower degree of resolution. Thus, the thermoluminescence dates from Venta Laperra and Pondra caves offer a minimum age for the decoration of these caves, and these are significantly older than expected (González Sainz 1999). Uranium series applied to calcifications at Altamira, Tito Bustillo, and Castillo (Pike et al. 2012) are surprisingly old, and the accuracy of this technique is still being debated.

In any case, it seems that artistic skills were not the result of a progressive learning throughout thousands of years of European Paleolithic art. Advances in dating techniques will allow us to reconstruct in a much more precise way the sequence of this first art of mankind.

Style, Territory, and Identity

The spatial settlement of hunter-gatherer groups in the territory is given by the combination of sedentary behaviors and a range of mobility. Within these parameters, social activities develop. In this sense, art is understood as a graphic code associated with a specific community and is an indispensable tool for the characterization of groups of Paleolithic hunter-gatherers.

In the Cantabrian coast, the graphic traditions of the Early and Upper Paleolithic were significant (Moure Romanillo 1994). This includes the open air rockshelters or sites decorated with deep engravings representing animal forming palimpsests and especially concentrated in the Nalón basin and the deep caves with red animal paintings composed of small digital dots arranged in pairs, whose main focus of which is found on the river Asón. The caves of the central part of the region have fine striated engravings which represent animal fur, which also present on pieces of portable art. In all cases the most common animal is the deer, accompanied by horses, aurochs, and bison. Traditionally these regional styles were interpreted as successive and independent but, in the light of the recent chronological findings, they could have overlapped in time, reflecting the presence in the territory of different human groups (Garate 2010).

By the end of the Upper Paleolithic, the Cantabrian regional particularities are replaced by some artistic interregional linkages encompassing also the Pyrenees and the Dordogne (Fig. 5).

Altitude Environments in Archaeology

Mark Aldenderfer
University of California, Merced,
Merced, CA, USA

Introduction

Because humans have evolved as a low-elevation species, to live and thrive at high elevations, our species had to develop physiological, genetic, and cultural adaptations to this extreme environment. Although it is probable that humans made seasonal forays into high-elevation environments, perhaps beginning in the Lower Paleolithic in Africa, the permanent occupation of high-elevation environments occurred relatively late in prehistory. The adoption and spread of plant and animal cultigens, along with acquired genetic adaptations, allowed high-elevation inhabitants, particularly in the world's high plateaus, to create complex polities.

Definition

High-elevation (or altitude) environments are defined as those at and over 2500 masl (meters above mean sea level). It is at this elevation that native lowlanders first experience hypoxia, which is the reduced partial pressure of oxygen. At sea level, for example, arterial blood is 97% saturated with oxygen; at 3000 m, it is at 90%; and at elevations between 4000 and 5000 m, saturation decreases by almost 30% when compared to sea level (Beall 2001: 426–428). Hypoxia has both direct and indirect effects on health status, reproduction and growth, nutritional status, and work capacity. These effects on human biology are differentially expressed across time and can be characterized as being of short-or long-term consequence. Hypoxia is the terrestrial environmental stressor that is least amenable to intervention and amelioration via cultural adaptations. The establishment of permanent elevations above 2500 m depended of the appearance of acclimatizations (phenotypic plasticity), true adaptation (the appearance of genes capable of overcoming the selective pressure of hypoxia), or some combination of the two.

High-elevation ecology is determined by a complex interaction of climate, altitude, and topography and can be characterized by five primary features (Aldenderfer 1998: 2–4): (1) environmental heterogeneity, (2) extremeness, (3) low predictability, (4) low primary productivity, and (5) high instability and fragility. High-elevation environments tend to be patchy in both space and time, and consequently, there is significant variability in the location, size, and duration of resource patches. At high elevation, two aspects of extremeness are important: cold temperatures and hypoxia. Even in tropical mountains like the Andes, cold is a constant problem, and humans must cope with cold by cultural adaptations that have significant material and energy costs, thus diverting resources from the subsistence quest. Hypoxia affects plant morphology and metabolic processes, which in turn affects primary productivity. The combination of cold, hypoxia, and aridity in high -elevation environments creates a context of low primary productivity. Only the most extreme deserts and polar environments of the planet have lower primary productivity than those at high elevation. Finally, high-elevation environments are highly susceptible to wind and rain erosion and extreme colluvial processes which can modify terrain, change stream courses, and destroy resource patches, thus contributing to the overall patchiness of the high-elevation landscape.

The stressors of hypoxia and cold likely had significant effects on the range of human *cultural* adaptations and historical outcomes of cultural evolution and change at high altitude. Constraints on fertility or exceptionally high neonatal mortality rates, for example, which are known to affect migrants to high elevation, may well have led to lower growth rates of highland populations, especially in the generations immediately following their founding by lowlanders. And since high-elevation peoples tend to have higher basal metabolic rates, they would have required on average more calories than comparable low-elevation peoples. This may in turn have had important effects on cultural strategies when dealing with problems relating to environmental packing, diet choice under restricted mobility, resource intensification, and both short- and-long-term changes in resource availability. Mobility strategies themselves may have been substantially affected due to demands imposed by basic caloric requirements as well as the greater work effort required to traverse rugged mountain topography. Although it is important not to cast these stressors in an overly deterministic role, they did have tangible effects on a variety of aspects of human life at high elevation.

There are relatively few places on the planet that exceed 2500 m in elevation (Fig. 1). Most are the peaks and surrounding high terrain of the mountainous regions of North America (the Alaska Range and the Rocky Mountains), Central America (including the Basin of Mexico),

Altitude Environments in Archaeology, Fig. 1 Shaded areas are above 2500 masl. The elevation of Greenland is due to the presence of an ice sheet

South America (the Andean chain), Europe (the Alps and Caucasus), the Middle East (Zagros), the Asian mountain systems (Himalayas, Tien Shan, Kunlun Shan, and Altai ranges), and Africa (peaks in Ethiopia and Kenya). Aside from the Greenland and Antarctic plateaus, which owe their elevation to massive glaciers and icecaps, there are three major plateaus at high elevation: the Ethiopian plateau, the Andean altiplano, and the Tibetan plateau.

Historical Background

The study of high-elevation environments in archaeology has been significantly undertheorized. Although archaeological research has been done in all of the world's high plateaus and surrounding mountainous regions, virtually no serious consideration of how the stressors of hypoxia and cold affected the ways in which these environments were first entered then permanently occupied. Clive Gamble's *Timewalkers* (1993) recognized high-elevation environments as extreme and noted that they were among the last places on the planet to be occupied permanently. However, there was no discussion of the physiological factors that would have challenged early inhabitants, and instead the ruggedness and difficulty of the terrain were emphasized.

Key Issues/Current Debates

There are two major areas of emphasis in modern archaeological studies of high-elevation environments: evaluations of the evidence for the initial peopling of the world's high plateaus and mountainous regions and debates about the timing of their permanent occupation.

Evidence for Early Entries into the World's High Elevation Regions

Ethiopian Plateau

It is possible that some of our hominin ancestors may have entered elevation zones above 2500 m as early as 1.5 mya along the Rift Valley rims near the southern margin of the Ethiopian plateau. Sites such as Melka Kunture (2300–2400 m), which contains Olduwan, Acheulian, and Middle Stone Age materials, also include the fragmentary skeletal elements of *Homo ergaster* and *Homo erectus,* and the Gadeb locality (2400 m), which contains Developed Olduwan and Acheulian materials dated between 1.5 and 0.7 mya, suggests the possibility that higher-elevations regions on the nearby plateau could have been utilized on a seasonal or temporary basis (Aldenderfer 2006). Acheulian-style hand axes and Middle Stone age artifacts have been found in surface contexts on the plateau at elevations up to 2300 m (Phillipson 2005). Vogelsang et al. (2018) report on the discovery of a buried site with Late Acheulian materials, including hand axes, in the Mount Dendi region of the central Ethiopian plateau at an elevation of ca. 3000 m. Unfortunately, no chronometric dating of the site has proven possible, but the investigators suggest an age between 500,000 and 200,000 years ago based on stone tool morphology. If confirmed by subsequent analysis, this would represent the earliest hominin entry into a high-elevation environment in the world. A much more secure date of an early presence on the Ethiopian plateau is reported by Ossendorf et al. (2019). At the Fincha Habera rockshelter, found at an elevation of 3469 m in the Bale Mountains, they report the presence of an assemblage of stone tools said to be typical of the Ethiopian Middle Stone Age along with the burned remains of giant mole-rats. The date of the materials ranges from 31,000 to 47,000 BP. The authors describe the rockshelter as "…a long-term residential site" but this interpretation is open to question. Nevertheless, it is the earliest securely dated high elevation site.

Andean Altiplano

The antiquity of an initial human presence on the Andean altiplano is constrained by the antiquity of the human presence in the New World. The only reliable archaeological data for the earliest site in South America is from Monte Verde, located in lowland south-central Chile and which is dated to between 14,220 and 13,980 cal BP (Dillehay et al. 2008). Recent research has considerably expanded our understanding of the timing of an early human presence in the Andes. Two sites are the earliest: Rademaker et al. (2014) at Cuncaicha, a rockshelter located at 4480 m in the south-central Andes of Peru, and which is dated between 12,400 and 11,400 cal BP. A second rockshelter, Cueva Bautista, located in the highlands of southwestern Bolivia at an elevation 3933 m, has similarly early dates as well which range between 12,700 and 12,100 cal BP (Capriles et al. 2016b). The earliest levels of Asana (3435 m) in southern Peru range in date from 11,710 to 10,511 cal BP (Aldenderfer 1998); slightly further to the south in northern Chile, three sites have early dates: Hakenasa (4100 m), 11,600–10,190 cal BP; Las Cuevas (4485 m), 11,720–10,300 cal BP; and Pampa el Muerto 15 (3174 m), 11,070–10,570 cal BP (Osorio et al. 2017). There remains some controversy about the routes by which these sites were occupied; a traditional model suggests that coastal foragers who occupied the Pacific shorelines began to explore the nearby highlands and eventually, became permanent residents (Aldenderfer 1998). A second model sees the high elevation dry puna as a "megapatch" that was exploited systematically from the north of the continent to the south (Osorio et al. 2017).

Tibetan Plateau

The lack of systematic research on the plateau has not prevented speculation on the timing of the initial entry of humans onto the plateau. Dates from 50,000 to 35,000 years ago have been postulated and were generally based on limited evidence that has subsequently been shown to be

incorrect (Aldenderfer 2011: 142). However, recent research has not only confirmed an early presence of humans on the plateau by at least 30,000 years ago but has pushed a possible initial entry back to the Middle Pleistocene. These discoveries, however, are not without controversy. The most secure of these discoveries is from the Nywa Devu site (4600 m) on the central Tibetan plateau that is dated between 30,000 and 40,000 years ago (Zhang et al. 2018). The excavators describe the site as a quarry for the procurement of lithic material. Aside from these artifacts, no other cultural materials were identified. The location of the site invites speculation what role this site may have served in a settlement system, but the investigators do not advance a hypothesis on this. A more problematic discovery is from the extreme northeastern margins of the plateau at the Baishiya site (3280 m; Chen et al. 2019). The report on the site describes a mandible (labeled the Xiahe mandible by the authors) dated to 160,000 years ago and attributed to a Denisovan phylogenetic status on the basis of proteins recovered from it. Artifacts described as of "Paleolithic" style are said to be present but were not described. The investigators make a number of strong claims about the site. They state "Our results indicate that archaic hominins occupied the Tibetan Plateau in the Middle Pleistocene epoch and successfully adapted to high-altitude hypoxic environments long before the regional arrival of modern *Homo sapiens*" (Chen et al. 2019: 409). The data presented support neither claim. As noted above, the site is on the extreme margins of the plateau and is at a slightly higher elevation than the valley floor below. It is more plausible that this site reflects a temporary use of the plateau margins from lower elevation base camps, a pattern seen much later in time on the northeastern plateau at sites such as Heimahe 1 (3210 masl) and Jiangxigou 1 (3330 masl) which date between 15,000 and 13,000 BP (Madsen et al. 2006). The temporary use of the margins of high elevation regions does not require genetic adaptations, and the authors offer no evidence of these aside from the assignment of the mandible to the Denisovans. Terms like "occupied" imply permanent residence, and until the type of use of the site is determined by the composition of the archaeological assemblage, the larger significance of the Xiahe mandible in relationship to the peopling of the plateau remains to be seen. These observations do not diminish the importance of the find, but they do place it into a broader context.

Other Mountain Regions

Many of the world's highest mountains are in the Northern Hemisphere and are characterized by strongly seasonal climates which include intense winter cold and significant snowfall. During glacial epochs, many of these mountain ranges could not have been inhabited or traversed during the winter. Consequently, human or hominin entry into these high-mountain environments, such as the Alps, Caucasus, Zagros, Altai, or Rocky Mountains occurs relatively late in prehistory. Richter (2006) notes that Neanderthals seasonally used rockshelters in the Swiss and Austrian Alps at elevations ranging from 1400 to 2100 m during MIS 3 times (roughly 57,000–29,000 years ago); Roustaei (2010) reports on Middle Paleolithic tools (dated by typology) in the Zagros mountains at elevations ranging from 2450 to 2800 m; although the low-elevation Dmanisi site in the southern Caucasus shows the presence of hominins in the region in the Lower Paleolithic, higher elevations, and then only at 2150 m at the Tsona site, are not entered until MIS 7 (243,000–191,000 years ago; Doronichev 2008); although the lower-elevation zones of the Rocky Mountains were apparently used by Clovis peoples (11,200–10,900 BP), defined by surface finds of projectile points, no excavated Clovis-era site has been discovered. There is evidence, however, of a Folsom presence dated to 10,600 BP (Jodry et al. 1996; Pitblado 2017).

Debates over the Timing of the Permanent Occupation of High-Elevation Regions

Although the data are limited, it appears that permanent occupations of the Ethiopian plateau at least by the end of the Pleistocene or the onset of the Holocene (Finneran 2008).

Despite continued controversy, a permanent occupation of the Andean altiplano is far better understood. Rademaker et al. (2014) have argued that Cuncaicha rockshelter was a base for foragers who lived permanently in this region of the altiplano. However, Capriles et al. (2016a) challenge this and argue that the materials recovered from the site do not clearly support a permanent occupation and instead are more consistent with a seasonal use of the site. According to Aldenderfer (1998), the Asana site in southern Peru was first used as a short-term logistical site monitored from low-elevation base camps but became part of a permanent high elevation settlement system around 9500 cal BP. Lindo et al. (2018), using ancient DNA extracted from human remains recovered from the Titicaca basin, postulate a separation of lowland versus highland peoples in the Andes around 9000 BP. Haas et al. (2017) using isotope data obtained from burials in the Titicaca basin (3800 m) shows that humans have been living permanently on the altiplano at least since 7000 BP. These studies demonstrate convincingly that domesticated plants and animals were not required for permanent life at high elevation in the Andes.

Controversies over the timing of a permanent occupation of the Tibetan plateau remain very much unresolved. Until recently, most researchers did not believe that hunters and gatherers could have lived on the plateau permanently. Chen et al. (2015) claimed that agriculture facilitated the permanent occupation of the plateau only after 3600 BP, and that any archaeological evidence dated earlier than that reflected sporadic and seasonal use. Meyer et al. (2017) using data from the Chusang site in central Tibet (4270 m) challenged that interpretation and demonstrated the site, dated between 7400 and 12,000 BP, was part of a settlement system that reflected a permanent occupation of the plateau. Although the authors made no claims for the nature of occupation at Nywa Devu, its location suggests that it may well have been part of an earlier settlement system. These arguments that postulate permanent occupation of the plateau perhaps by 30,000 years ago are supported by analyses of the genomes of modern Tibetans (Lu et al. 2016).

As previously noted, the claims about a permanent occupation of the plateau at the Baishiya site are not credible.

Future Directions

As with many research questions in archaeology, more data will be required to begin to resolve many questions regarding the peopling of the world's high places and the timing of permanent occupation upon them. Research strategies that focus upon accessibility and the timing of possible openings onto plateaus from surrounding lowlands offer some real promise. So-called ice patch archaeology – the examination of areas once covered by permanent snow that have begun to melt as global warming intensifies – is beginning to provide new data into specific routes into mountainous terrain or the locations of possible foraging territories. The discovery of Ötzi, the frozen remains of a person who died in a high alpine setting (3210 m) around 5200 BP in what is now the Austrian-Italian border, is a dramatic example of what may be discovered as research intensifies.

Another line of evidence that may provide some insight into high-elevation genetic adaptations is ancient DNA (aDNA). If skeletal remains of sufficient antiquity and conditions of preservation can be located, it may be possible to examine these samples for the presence of genes and alleles thought to promote adaptation to hypoxia.

Amazonian Dark Earths: Geoarchaeology

Manuel Arroyo-Kalin
Institute of Archaeology, University College London, London, UK

Introduction

Amazonian Dark Earths (hereinafter ADEs) are expanses of anthropogenic soils that formed on generally nutrient-poor upland soils of the Amazon basin during pre-Columbian times. Expanses of ADEs range from <1–80 ha, and overall agricultural aptitude is higher than the vast majority of soils in the region. These soils are much sought after by local farmers who use them to grow specific crops. Most of the documented expanses of ADEs are found on Tertiary-age sediments located in riparian and interfluvial positions of the Amazon basin. However, instances are also reported on Quaternary alluvial sediments and on human-made earthworks, highlighting that the formation of these soils was an outcome of specific forms of pre-Columbian settlement. The discovery of ADEs alongside the main waterways of the region has been a crucial Rubicon for Amazonian archaeology: these soils record the effects of pre-Columbian indigenous societies' creative manipulation of environmental affordances. Thus, they highlight that human inhabitation of the Amazon basin was, and is, much more than efficient adaptation to environmental limitations. Their ubiquity provides strong evidence for the existence of more sedentary and demographically denser indigenous societies in the Amazon basin before European colonization. Moreover, examined from a strictly archaeological perspective, ADEs are one of the best archaeological signatures of sedentary occupations in a region with limited archaeological preservation potential. ADEs are *sui generis* archaeological artifacts of extraordinary relevance for present-day concerns: soil scientists are currently studying the properties and formation of ADEs in order to develop techniques of soil amelioration that permit recuperation and amendment of degraded and infertile soils.

A

Definition

ADEs collectively refer to circumscribed expanses of organically enriched mineral soils found mostly within the non-flooding terrain of the Amazon basin. Expanses of these soils vary in size, shape, and location: linear expanses have been reported as patches extending over hundreds to thousands of meters along *terra firme*(non-flooding) bluffs that overlook the major waterways of the basin. However, smaller patches, either oval in shape or draping the horizontal surface of the landform on which they are located, also exist on relict floodplain locations, on *terra firme* areas adjacent to alluvial lakes and flooding forest, on *terra firme* interfluvial terrain away from large rivers, and on alluvial sediments. Moreover, soil horizons with similar characteristics are reported on both shell middens and artificially constructed pre-Columbian mounds found in flooding landscapes of the Amazon basin and beyond.

The topsoil of ADEs (the A horizon) is generally darker (grey, brown, or ink black in color) and deeper (not infrequently reaching down to 60 cm) than the thin A horizons of regional soils. Studies distinguish between *terras pretas* (black earths), i.e., pottery-rich dark soils with a deep A horizon, and *terras mulatas* (brown earths), larger surrounding or adjacent expanses of darkened soils whose surface horizon lacks archaeological artifacts but whose nutrient status is intermediate between *terras pretas* and the broader soilscape (Sombroek 1966). Many scholars consider this contrast to reflect a distinction between sedentary pre-Columbian settlements and associated outfields. The vast majority of studies of ADEs concentrate on settlement-related *terras pretas*. These studies demonstrate that compared to the underlying B horizon or comparable adjacent soils, the A horizon of ADEs shows a higher cation exchange capacity, a more basic pH, and higher concentrations of, among others, organic carbon, calcium, phosphorus, manganese, potassium,

barium, copper, manganese, strontium, and zinc. Estimates of black carbon contents using molecular markers, such as benzenepolycarboxylic acids, suggest that the A horizon of settlement-related ADEs occludes up to 70 times more pyrogenic carbon (charred plant matter, i.e., charcoal) than adjacent Oxisols. This observation has been marshalled to suggest that high black carbon concentrations are key to the high organic matter retention of these soils (see Glaser and Birk 2011 for a recent review).

Historical Background

Amazonian Dark Earths were first described in nineteenth-century Brazil as "Terra Preta de Índio" (Indian's Black Earth) or simply as "terras pretas", the reference to "Indians" being a reflection of the fact that abundant pottery shards of evident pre-Columbian age could be seen on the surface. An anthropic origin for ADEs was advocated in these first descriptions: pioneering geologists like Smith and Hartt unhesitatingly related cultivated ADE patches to villages of former indigenous peoples (Myers et al. 2003). The results of the first soil chemistry analyses conducted on ADEs allowed Katzer (1903) to argue that their high fertility was the result of unusual concentrations of charcoal and decomposed organics in the fine earth fraction, properties which he argued had also made them attractive to farmers in the past. As early as the 1920s, ethnologist and archaeologist Nimuendajú (see Neves 2004) noted that their geographical distribution and associated archaeological remains (including artifacts, earthworks, and roads) suggested they had originated in densely populated, sedentary pre-Columbian settlements.

For the first part of the twentieth century, however, these opinions remained isolated. Nimuendajú's archaeological research went unpublished and, more significantly, was beyond the intellectual web of earth scientists until the mid-1960s. The size of farmed expanses in the Brazilian Amazon, the fact that many local farmers did not recognize their human-made origin, a lack of clear-cut evidence for their contemporary formation, and the scant attention accorded to them by important Amazonian archaeologists (see below) led some researchers to advocate a variety of "geogenic" models for their origins. In broad outline these models argued that ADEs are patches of fertile soils that formed from localized, non-anthropogenic accumulations of organic and/or mineral materials of fossil, volcanic, or peaty origin. However, Klinge (1962) argued that high total and soluble phosphoric acid concentrations of ADEs evidenced an anthropogenic origin. In parallel, Hilbert (1968) whose archaeological research documented the co-occurrence of dark earths and ceramic archaeological remains along the main rivers of the western half of the Brazilian Amazon, observed that ADEs formed on different types of Oxisols (Red and Yellow Latosols in the Brazilian soil classification). Like Nimuendajú, he suggested that ADEs resulted from long-lived settlement.

It was undoubtedly soil scientist Wim Sombroek's (1966) interpretation of the physicochemical characteristics measured in settlement-related ADEs located on the Belterra plateau (near Santarém, Brazil) that convincingly refuted geogenic models for their origin. Sombroek pointed out that the overall topography and drainage of the plateau were incompatible with suggestions that organic material had accumulated in small water bodies. He next noted that instead of the random spatial distribution to be expected from a natural phenomenon, the landscape position of ADE expanses suggested deliberate selection of areas suitable for the invigilation of navigable waterways. He then reported particle size and x-ray diffraction data that evidenced the same overall texture and kaolinitic parent material in *terras pretas* and neighboring soils, effectively overruling a source in volcanic debris. Finally, he enunciated the distinction between *terras pretas* and *terras mulatas*, i.e., between settlement-related anthrosols and settlement-peripheral anthrosols, and presented distributional evidence that expanses of the former were often associated with much larger surrounding or adjacent areas of the latter. It is fair to say that Sombroek settled the matter of anthropogenic *vis-à-vis* geogenic origins in the 1960s.

Although Sombroek's work inaugurated the modern era of studies of ADEs, discussions of Amazonian pre-Columbian history did not initially take stock of their presence or ultimate significance. This lack of attention was not trivial in the face of contrasting understandings of pre-Columbian societies advanced by leading scholars of the day: Betty Meggers (1971) militantly disregarded suggestions that Amazonian upland soils could be made fertile and thus envisioned a low ceiling for sedentism and demographic growth based on the retroduction of ethnographically observed slash-and-burn agriculture. Donald Lathrap (1970) placed his weight behind the suggestion that the crop base of large pre-Columbian populations would have relied on intensive cultivation of rich alluvial sediments. While some argued that the agricultural aptitude of upland soils was not *per se* low nor necessarily unchanging (Carneiro 1983), this lack of attention to Sombroek's findings all but blinded archaeologists to the possibility of creative manipulation of environmental affordances in the past until the 1980s (Herrera et al. 1980–1; Eden et al. 1984; Andrade 1986; Mora 1991), when pioneering pedo-archaeological investigations in the Colombian Amazon highlighted the part that ADEs could have played in permitting denser populations in pre-Columbian times. On the other hand, Sombroek's research was a crucial intellectual referent for the first systematic survey of ADEs in the Brazilian Amazon, led by geographer Nigel Smith (1980). Significantly, Smith presciently surmised that the dark color of these soils was a result of the deposition of comminuted charcoal and argued they were the correlates of the large settlements that had been sighted by European explorers in the sixteenth century. Recognition of their ubiquity, in turn, permitted links with studies of Amazonian resource management – specifically practices resulting in deliberate environmental alteration (Posey 1984) and/or the presence of biotic legacies in the landscape (Balée 1989). These inferences eventually prompted a reassessment of geographers' arguments about pre-Columbian settlement patterns and population density (Denevan 1992, 1996). It is accurate to say that since the late 1980s and 1990s, ADEs have become an increasingly more important component of archaeological arguments about pre-Columbian Amazonia (Heckenberger et al. 1999; Petersen et al. 2001; Arroyo-Kalin 2010a).

Key Issues

The Makeup of ADEs

Many of the concentrations of edible or useful fruit trees marshalled by Balée (1989) as evidence of anthropogenic disturbance grow on expanses of ADEs (see also Junqueira et al. 2011). Some researchers have considered ADEs as remains of pre-Columbian house gardens produced by the deliberate composting of settlement residues (Andrade 1986; Myers 2004), others perceive them as an outcome of the accumulation, perhaps also management, of waste associated with settlements (see review in Erickson 2003; WinklerPrins 2009; Schmidt 2013, in press), yet others postulate that alluvial inputs make these soils more productive (Herrera et al. 1992; Woods 1995), and still others emphasize the role that pottery production may play in understanding their makeup (Lima et al. 2002; Schaefer et al. 2004; Sergio et al. 2006). It is evident that these opinions do not necessarily exclude each other, especially because a single, Amazon basin-wide account of these soils' formation processes is unlikely to exist. This explains in part the appeal of the "kitchen midden" model (Sombroek et al. 2002), which suggests that a combination between the decomposition of excrements, household garbage, bone, and organic constructions, and the concentration, of ash and charcoal derived from ground-level fires are the most important inputs leading to the formation of settlement-related ADEs. A rise in soil pH associated with organic waste is argued to permit the formation of resistant organo-mineral complexes and thus augment the retention of a more stable pool of organic matter (Sombroek 1966); larger quantities of pyrogenic carbon are considered to provide more ubiquitous sorption sites for metals; a combination of illuviation and faunal mixing of comminuted and/or decomposed constituents is considered

responsible for homogenizing these inputs and for the strong melanization that characterizes these soils (Vacher et al. 1998; Kern et al. 2004; Topoliantz and Ponge 2005); both organic and inorganic inclusions are thought to become metabolized by soil microbes and stabilized through humification (Glaser and Birk 2011).

Micromorphological studies have been crucial to ascertain some of these processes as well as the ubiquitous presence of microscopic charcoal, bone, and pottery fragments in ADEs. Soil micromorphological methods were initially deployed by soil scientists (Lima et al. 2002; Schaefer et al. 2004) to compare *terras pretas* and nearby Oxisols. This study permitted linking the aforementioned anthropogenic inclusions and enhanced elemental concentrations. A geoarchaeological study using soil micromorphology (Arroyo-Kalin 2008b, 2010a, 2012; Arroyo-Kalin et al. 2008) expanded these results significantly. By comparing ADEs from within archaeological sites and contrasting observations between clayey- and sandy-textured ADEs from different archaeological sites, it showed that high levels of nutrient enhancement covary with the presence of microscopic inclusions (especially charcoal and bone), highlighted that high densities of microscopic pottery fragments and baked clay are reflected in high magnetic susceptibility values for these sediments, and presented empirical evidence to distinguish between settlement-related *terras pretas* and settlement-peripheral *terras mulatas*. *Terras mulatas* were found to contain a significant volume of microscopic charcoal (lower than *terras pretas*) but, despite high nutrient status, only negligible fragments of microscopic bone, pottery, or burnt clay. Magnetic enhancement of *terras mulatas* has been interpreted as evidence that soil microscopic charcoal did not originate *ex situ* but from repeated near-surface burning associated with past management. Coupled with micromorphological observations suggesting scraping, raking, and/or churning of the soil, this research provides important support for Denevan's (2004) suggestion that *terras mulatas* are the result of spatially concentrated, fire-intensive cultivation practices in pre-Columbian times. It also emphasizes that settlement-related ADEs bear the material signatures of midden material, house floors, and other activity areas.

From a geoarchaeological perspective, important questions arise about the buildup of settlement-related ADEs, which are anthropogenic cumulic soils that in many cases lack a clear source of sediments nearby. Micromorphological analysis accords a role to bulking-up of the sand- and silt-sized fractions by large quantities of microscopic inclusions of anthropic origin, to mixing by soil fauna, and, indirectly, to ash deposition (Arroyo-Kalin et al. 2008). These observations shed light on two conceptual models for ADE horizonation: Vacher et al. (1998) suggest that vegetation clearance associated with the implantation of settlements would lead to destruction of organic litter, after which inhabitation-related production of organic and mineral inputs and the modification of mineral surfaces through trampling, soil removal, and other activities would lead to the formation of a modal O-A-B soil profile with clearly established eluvial and illuvial subhorizons. The upper subhorizon would be directly affected by settlement activities and the lower one would accumulate inputs from the settlement surface. Visible differences between these subhorizons would be obliterated as the lower subhorizon becomes saturated with pigmenting soil constituents, effectively resulting in melanization. At site abandonment, a new mineral surface (A horizon) would be developed through upwards translocation of sediments by soil fauna, obliterating settlement-related sedimentary structures (e.g., compaction) and interring artifacts in the organically enriched sediment matrix. Woods (1995), in contrast, highlights that the accumulation of organic and mineral material would tend to bury the original surface, resulting in rising of habitation surfaces as subsequent occupations takes place. Given a modal O-A-E-B soil profile, he argues that organic inputs would result in an enhancement of the activity of soil fauna as well as strong melanization of the new A horizon, transforming the sediments of the original A-E-B sequence into a transitional AB horizon. Further sedimentation associated with continued habitation would tend to result in

repetition of the same process, i.e., buildup at the surface and down mixing as a result of increased activity of soil fauna. While Woods' model is particularly useful to explain the thick A horizons most commonly noticed by soils scientists, there are elements in both models that resonate with empirical observations: ADEs should not be understood exclusively as thick A horizons that have expanded downwards but as an outcome of the accumulation of settlement debris, the effects faunally induced burrowing, mixing, and/or churning of soil material; of the upwards or "conveyor" translocation of sediments from lower in the deposit; and of a higher overall deposition of organic matter (Arroyo-Kalin 2008b).

The Making-Off of ADEs

In his classic review of Amazonian pre-Columbian community patterns, Myers (1973) argued that the larger and more complex settlement layouts that could be derived from ethnographic and ethnohistorical sources – single-family house communities, multi-family rounded or circular houses, plaza-centered groups of houses (including cases of multiple malocas around a plaza), and linear groups of houses strung alongside rivers and lakes – were all characterized by scrupulous maintenance of the patios, plazas, or circular plazas within, behind, or around which dwellings were located. These maintenance practices resulted in debris accumulating as secondary refuse in either linear middens behind rectilinear rows of houses or in ring-shaped middens around other types of settlements (from single and multi-family house-based settlements to plaza-centered groups of houses). Erickson's (2003) recent survey of the ADE formation literature reexamines Myers's (1973) classic survey and suggests that ADE expanses could result from a combination between specifically shaped refuse accumulations, remobilization of enriched soils once they have formed, and overlapping occupations characterized by different settlement layouts. These suggestions are borne out by the compounded results of different ethnographic studies in Amazonia: Deboer and Lathrap's (1979) ethnoarchaeological study of San Francisco de Yarinacocha, in the Peruvian Amazon, shows that secondary refuse resulting from constant sweeping and raking of household and plazas/patios should, under ideal conditions, accumulate in settlement-peripheral middens and (to judge from the settlement plan they present) specific activity areas such as food preparation and pottery firing areas (see also Siegel and Roe 1986). Zeidler (1983) describes a 3-year-old Achuar dwelling as a thatch-roofed oval area of some 160 m^2 enclosed by walls formed by upstanding peach palm logs. He observes that the position of debris within the house reflects, first, gender-ordained, communal, and personal activity areas and, second, maintenance of clean spaces through sweeping. However, he also notes that the periodicity of sweeping opens up opportunities for artifacts to become interred as a result of trampling, a process that is assisted by sedimentation of ash, charcoal, and burnt soil produced by and accumulated adjacent to combustion features. In the upper Xingú region, research along the southern periphery of the Amazon basin has highlighted circular plaza-centered villages surrounded by rings of dwellings as contexts for the formation of ADEs (Heckenberger 2005; Schmidt 2013, in press). Chemical and physical analyses of a ringlike string of elevated rubbish middens behind house structures as well as house sediments and plaza sediments show the lowest values of pH, organic matter, phosphorus, calcium, potassium, manganese, magnesium, and sodium in the latter areas, intermediate values within abandoned houses, and high values within middens. Middens form distinctive patterns on the landscape consisting of linear mounds along backyard edges and trails. These are used for the cultivation of home garden crops but can also be levelled to place houses on them. Comparable data are presented by Hecht (2003) at the Kayapó settlement of Gorotire, which identifies different types of middens beyond plazas and houses and records comparatively higher concentrations of key elements as a result of planned waste management. Silva's (2003) study of an Asuriní village similarly shows how regular maintenance of public spaces produces large middens behind houses, some being deliberate pilings of large

amounts of debris and others more incidental accumulations. In northwest Amazonia, early-twentieth-century ethnographic descriptions show thatch-roofed longhouses enclosing spaces internally divided into communal areas used for meals and transit, compartments for nuclear families, and areas in which manioc processing takes place. Fireplaces of different kinds and purposes were frequently used in different parts of the longhouse, resulting in the production of charcoal and ash. Many accounts suggest that the interiors were swept regularly, sometimes accompanied by wetting of the otherwise dry floors (Koch-Grünberg 1995 (1909)). More recent observations (Arroyo-Kalin, field notes) suggest that floors of thatch-roofed structures are characterized by buildup of sediment in which significant amounts of organic debris, ash, and charcoal accumulate. Roofed precincts restrict the transportation of airborne sediments permitting, among other things, the accumulation of soot particles on the underside of roof thatching (in new houses, this is encouraged to increase water-proofing). A number of different researchers (Neves et al. 2003, 2004; WinklerPrins 2009) point to various forms of localized "dooryard" burning of organic debris that could result in localized, within-settlement concentrations of charcoal and other debris. Other activity areas of potential interest for the formation of ADEs are smoldering fires under racks used for smoking fish and, perhaps most intriguingly, areas in which pottery tempered with *caraipé* (obtained by ashing the bark of *Licania octandra*) was produced. The *caraipé* link deserves more focused research given that it could permit linking ADE formation to particular ceramic techno-sylistic traditions. All in all, it is clear that a variety of contexts for the formation of ADE must be considered.

ADEs in Space and Time

An up-to-date map of the spatial distribution of reported expanses of ADEs is being developed as a Google Earth map (WinklerPrins and Aldrich 2010). The overall distribution suggests ADEs are ubiquitous in the Amazon basin but, on the whole, less frequent or underreported as one approaches the westernmost lowlands of the Amazon basin. In terms of occupations, the oldest reported ADEs are associated with c. 3rd millennium BCE preceramic occupations of the Massangana phase, Jamari river, in the upper Madeira basin, Brazil (Miller 1992). However, the vast majority of occupations include ceramic remains and charcoal that date from around or after 0 CE and, in many instances, from around 500 CE. Most of these occupations peak around or after 1,000 CE (Arroyo-Kalin 2008a; Moraes and Neves 2012). Some controversy has existed about the extent to which *terra preta* sites reflect continued inhabitation as opposed to overlapping short-lived occupations (Meggers 2001; DeBoer et al. 2001; Heckenberger et al. 2001; Neves et al. 2003, 2004; Neves and Petersen 2006). A comparison between the 14C dates of soil-embedded microscopic charcoal and macroscopic charcoal associated with archaeological remains shows that the pyrogenic carbon pool of *terras pretas* is coherent with the most intense human occupations inferred from archaeological evidence (Arroyo-Kalin 2012). At the Manduquinha site, a relatively small ADE expanse occupied over a period of approximately 300 years prior to European contact, horizontal variability in elemental concentrations of the A horizon is interpreted as evidence for areas of transit, middens, dwellings, and shells heaps, effectively suggesting a relatively stable settlement layout persisted during occupation (Kern et al. 2004). Studies of multicomponent sites (e.g., Heckenberger et al. 1999, Neves 2003, Mora 2003, and Moraes 2006) support Woods' contention that ADEs are accreting deposits in which numerous occupations are recorded. Thick A horizons in ADE are generally associated to anthropogenic enrichment of multiple surfaces and subsequent mixing by soil fauna, sometimes appearing as subhorizons to other earth scientists (Arroyo-Kalin 2008b). Evidently this suggests that many of the best-known ADE exemplars are large sites with protracted and intensive occupation histories. However, less-evident, perhaps incipient anthropogenic horizons are found associated with occupations that reach back to the early to mid-Holocene (Arroyo-Kalin 2010a).

Future Directions

While much recent literature has emphasized the unique Amazonian character of these soils (Lehmann et al. 2003; Glaser and Woods 2004), archaeological investigations show that similar anthropogenic modifications are found beyond the Amazon basin, for instance, in the north of Colombia, in the Orinoco basin, in the Guianas, and in subtropical areas south of the Amazon basin proper. This has led some to propose the need to reconsider the distribution of anthropogenic dark soils of pre-Columbian origin within the broader geographical context of the Neotropics (Graham 2006). Even casual perusal of studies from further afield highlights that anthropogenic soils and sediments have been linked to a very broad variety of situations, i.e., underscores the need to examine ADE formation processes with attention to historical regional specificities. Notwithstanding, the significant appeal of their study in the Amazon basin ultimately resides in a heritage of archaeological interpretations that regards the Amazon basin as hostile to population growth and sedentism. ADEs lay to rest this suggestion and effectively tackle down the received truth that soil fertility was an insurmountable limit for pre-Columbian populations.

Amazonian Dark Earths are prized to this day by farmers because they achieve higher yields of staple lowlands cultivars such as manioc, permit the growth of acid-intolerant crops such as maize, and concentrate a high diversity of edible/useful fruit trees. The overall spatial distribution of ADEs might suggest co-occurrence between these soils and regions where bitter manioc is cultivated (Arroyo-Kalin 2010a; Fraser et al. 2011). However, more intensive archaeological survey is required to ascertain broad patterns of regional distribution as well as to determine any significant temporal gradients in their formation. Detailed consideration of their variability and associated plant and animal fossil assemblages is called for to answer a number of archaeological research questions: given the ubiquity of microscopic bone fragments and the fact that bone apatite is a source of P and Ca, can fertile ADEs be linked to the ability of past populations to tap into abundant faunal resources? If this is the case, then new and interesting questions arise regarding the feedback mechanism between fishing, the main source of protein in Amazonia, and the development of fertile agricultural soils (Arroyo-Kalin 2010b). A further question can be asked: to what extent have we grasped the full variability of the ADE phenomenon? Here it is crucial to take into consideration the little that we know about the variability of intra-settlement and, especially, settlement-peripheral soils (*terras mulatas*), which can be expected to vary according to broad precipitation patterns (Arroyo-Kalin 2012). One might also ask: were some of the well-developed expanses that we see today recycled for crop cultivation in the pre-Columbian past? Did they play a role in permitting the cultivation of certain crops? Were they dump heaps for the domestication of autochthonous Amazonian lowland crops? What does the spatial patterning of known occurrences indicate in terms of pre-Columbian population density and livelihoods (Arroyo-Kalin 2010b; cf. McMichael et al. 2012)? To what extent did increased soil fertility in ADEs lead to specific locales becoming more contested by pre-Columbian populations (Arroyo-Kalin 2008a)? Such questions can only be answered through interdisciplinary research that includes archaeological perspectives: it is otherwise impossible to establish basic spatiotemporal parameters that permit examining ADEs as historical outcomes of multiple processes. In conclusion, it can be stated that ADEs provide a paradigmatic example of a trans-generational and cumulative transformation of the landscape – one with incidental *and* deliberate components – in an environment long regarded as impenetrable. Consequently, the study of ADEs ultimately angles on the increasingly more significant role that human niche construction (Laland et al. 2000) – as a long-term process associated with cultivation, husbandry, and sedentism – is set to play in archaeological thinking in coming decades.

> Entre les temps différents de l'histoire, la longue durée se présente ainsi comme un personnage encombrant, compliqué, souvent inédit. L'admettre au coeur de notre métier ne sera pas un simple jeu, l'habituel élargissement d'études et de curiosités. Il ne s'agira pas, non plus, d'un choix dont il serait le seul bénéficiaire. Pour l'historien, l'accepter c'est se prêter à un changement de style, d'attitude, à un renversement de pensée, à une nouvelle conception du social.
> Braudel (1958)

Introduction

Shellmounds (also known in Brazilian archaeology as sambaquis), understood as archaeological sites whose stratigraphic matrices are composed predominantly by shells, are found in fluvial and coastal contexts throughout the planet. They can

be understood as meaningful places (Zedeño and Bowser 2009) where human occupation has persisted for millennia (Schlanger 1992). The convergence of factors which led to the emergence and countless waves of reoccupation of these sites has been studied since the origins of archaeology (Steinen 1886, 1894). In the Amazon basin, the earliest shellmounds date at least to the eighth millennium BP and occur in three contexts: in the Lower Amazon (LA), along the Estuary and Coastal Areas (ECA), and in Southwest Amazonia (SWA), along the tributaries of the upper Madeira River (Fig. 1). In common, these sites share some of the earliest ceramics produced in the New World. Outside of the Amazon, there is also a correlation between early ceramic production and shellmound construction in places such as northern Colombia (Reichel-Domaltoff 1985) and Southeastern United States (Sassaman 1993, 2004a, b). The reason why such a pattern developed is one of the most interesting questions of New World archaeology.

The Long History of Shellmounds in the Amazon

The distance between the areas with known occurrences of shellmounds in the Amazon is considerable, and one could surmise that they represent distinct processes of occupation. However, their common traits in terms of chronology, settlement patterns, and technological histories of their ceramics are becoming increasingly more evident with the development of archaeological research in these sites.

Early evidence of ceramics in Amazonian shellmounds is reported in the literature (Evans and Meggers 1960; Simões 1981; Williams 1981, 1997; Meggers 1987, 1997; Roosevelt et al. 1991;

What do Amazonian Shellmounds Tell Us About the Long-Term Indigenous History of South America?, Fig. 1 Sites with ceramics dating back to 8000 cal BP and the shellmounds' occurrence areas estimated by the known sites in Amazon

Roosevelt 1992, 1997; Hoopes 1994), and it is noteworthy that early ceramics are consistently found in the basal strata of Amazonian shellmounds. As will be seen below, these early ceramics always appear as vestiges of simple industries which started to incorporate technological innovations at some point in the Middle Holocene, including the adoption of specific attributes shared among distant contexts: this occurs in Taperinha, Monte Castelo, in the Xingu sites, the coastal sites in Pará and the Guyanas, as well as in the ancient ceramics of the Colombian and Ecuadorian coasts and even in Panama (Meggers et al. 1965; Reichel-Domaltoff 1985; Hoopes 1994; Oyuela-Caycedo 1996).

Roosevelt (1995) was the first to show that there are no preceramic strata in Amazonian shellmounds. These sites are always built on topographically salient areas, which gradually received low amounts of sediments until people started to erect an earth mound, after which constructive layers were added with shells. Ceramic remains are present throughout the whole stratigraphic matrix. The scant available data shows that ceramics are present at the basal strata of the mounds, even if in very simple form or in low density. An eventual preceramic component in this type of site would, therefore, be an exception (but see Williams 1997 for another interpretation). This suggests that contexts for early mound building were correlated with the clay experimentation from the beginning.

Amazonian shellmounds are located in environments where high diversity of resources is available along permanently or seasonally flooded areas such as floodplains and swamps. Shared characteristics are also seen in changes observed in the uppermost stratigraphic layers, where variations in settlement patterns are associated with differences in ceramic technology, mound-building activities, and, consequently, changes in the use of these places throughout the Middle Holocene. There are also recurring occupations from the Late Holocene, sometimes after chronological gaps in the sequences. Finally, indigenous people have seasonally occupied some of these places until the present. Thus, shellmounds can be seen as persistent places where archaeology provides data about continuity and change in the long-term indigenous history (LIH) of the Amazon since at least the Early Holocene.

Exploring the Similarities Among Amazonian Shellmounds

The area definitions proposed here are based on different criteria: LA and ECA for the diverse geoenvironmental contexts where they are localized, whereas SWA is a more isolated from other regions where fluvial shellmounds occur. A divergence in the malacological building materials used in each region exists, since bivalve mollusk shells are predominant in LA and ECA, but gastropod shells are more prominent in SWA. Distance and material differences group these three areas of occurrence into two isolated sets of sites, those in the west and those in the east. Despite this, the attributes shared by known Amazonian shellmounds permit exploring them as a single set of sites under formation throughout the Middle Holocene, allowing an understanding about the history of Amazonian landscape management from then until the present day (Fig. 2).

The Taperinha and Lower Xingu Sites (LA)

Taperinha is located adjacent to the floodplain of the Amazon River, downstream from the city of Santarém. The site was initially researched by Canadian geologist Charles Hartt in 1870–1871. Hartt recognized that the place was an archaeological site and suggested its old age due to its location next to an abandoned channel of the Amazon (Hartt 1885). More than 100 years later, Anna Roosevelt continued the research started by Hartt, seeking to test the hypothesis that contexts dating back to the Early Holocene could be excavated in the site (Roosevelt 2009). Taperinha is located on a ledge of dry land adjacent to the river's floodplain, with ready access to lakes, swamps, and natural channels. The site is 50,000 m^2 and over 6 m high, built on a beach (Roosevelt 1999), and, like Hartt had already noticed, ceramic fragments were found all the way to the basal layers. These were later dated to

What do Amazonian Shellmounds Tell Us About the Long-Term Indigenous History of South America?, Fig. 2 Chronology of Amazonian shellmounds from the 150 available radiocarbon ages (Simões 1981; Williams 1981; Roosevelt et al. 1991; Perota 1992; Perota and Botelho 1992; Hoopes 1994; Roosevelt 1995; Gaspar and Silveira 2000; Bandeira 2008, 2012; Miller 2009; Lombardo et al. 2013; Canto Lopes 2016), calibrated (Hogg et al. 2013) and quantified by occurrence areas

around 8000 cal yBP (all ages mentioned below are calibrated. From here on just BP), providing the earliest dates for ceramics in the Americas (Roosevelt et al. 1991; Roosevelt 1995, 1999, 2009). The site was occupied by relatively large and stable groups who carried out intensive fishing of fish and shellfish in the river, lakes, and streams of the region. The technology of early Taperinha ceramics (Fig. 3) was described based on 383 fragments identified in 48 different strata, composed by shells, charcoal, seeds, bones, and lithics (Roosevelt et al. 1991; Roosevelt 1999).

The ancient presence of ceramics in the Taperinha region is also supported by similar data from the Caverna da Pedra Pintada rockshelter (Roosevelt 1995), which would indicate the presence of early ceramics in other kinds of archaeological sites besides sambaquis, although other sites with ceramics dated to the transition from Early to Middle Holocene have yet to be found.

Ceramics of the basal strata are tempered with grit, sand, and, in a few cases, shell (Roosevelt et al. 1991; Roosevelt 1999). Vessel shapes are gourd-like and simple open bowls. Vessel shape and the presence of carbon soot in some sherds may imply the preparation and consumption of food (Oliver 2008). Eleven fragments evidenced incised or punctuated decoration (Roosevelt 1992, 1999). Lithic instruments in the same strata include hammerstones, flakes, grinders, and fire-cracked rocks. Other artifacts, such as scrapers of turtle bone and shell, are also reported (Roosevelt et al. 1991). Other than ceramic chronology and some stratigraphic details, there is little further information about the site. From the profile drawings, it can be seen that the basal strata shows the record of an earth mound upon which the shellmound was built. The switch from earth to shellmounding marks also a change in habitation and funerary patterns (Roosevelt et al. 1991; Roosevelt 1992, 1995, 1999, 2009).

What do Amazonian Shellmounds Tell Us About the Long-Term Indigenous History of South America?, Fig. 3 Taperinha ceramics from (**a**) Hartt (both sides) and (**b**) Roosevelt excavations. Collection of the Technical Reserve of Archaeology Mario Ferreira Simões, Museu Paraense Emílio Goeldi/MCTIC. (Photos: Elisângela Oliveira)

Taperinha's occupation persisted for a long period after early ceramic production. Overlaying early ceramic strata related to the earth matrix, there is a thick accumulation of shells composed of multiple strata dated to the Middle Holocene and, above it, a later stratum of Santarém ceramics associated with anthropic dark earths, or *Terras Pretas de Índio*, the latter dated to the early second millennium AD (Roosevelt 2009). Hartt had already recorded that the shellmound was covered by a stratum of dark soils with ceramics similar to ones found on other sites in the area.

Following earlier hints by Bates (1863) and Agassiz (1868), Hartt (1885) also mentioned the presence of other shellmounds in the LA region. Hilbert (1959, 1968), following Protasio Frikel, published data on Ponta do Jauari, also a shellmound located in the Santarem region, where Zone-Hachured ceramics were found overlapping Mina tradition layers. In the 1970s, excavations took place in Guará I and II sites in the lower Xingu River (Perota and Botelho 1992, 1994), and the available data indicates that around 3000 years BP ceramic materials related to the Mina tradition can be found in these shellmounds. They are broad-based sites, formed by the interdigitation of clay and sandy layers. Mina ceramics persist on the intermediate layers, where bivalve shells abound. The chronology also points to a more recent Mina tradition in the region. In fact, the most recent Mina tradition dates were recorded at the Guará I (Perota and Botelho 1992, 1994) and Uruá sites and are situated around 550 years BP (Silveira et al. 2008). The data reported seems to indicate that the old pattern of reoccupations verified at the base of other sites also occurred there. These sites, therefore, are also palimpsests that document the regional extent and persistence of the Mina tradition in the Lower Amazon.

The Mina Tradition Sites (ECA)

Shellmounds with Mina tradition ceramics were first cited (Baena 1839; Barbosa Rodrigues 1876) and described (Ferreira Penna 1876, 1877) in the nineteenth-century literature, from the lower Tocantins River to the mouth of the Amazon River. Further work done in Guyana in the 1950s identified similar sites as well with ceramics denominated as Alaka (Evans and Meggers 1960; Williams 1997). In the 1960s and 1970s, dozens of shellmounds and open-air sites with Mina ceramics were mapped and excavated at the Atlantic coast east of the mouth of the Amazon (Simões 1981), where ceramics were classified in

five phases (Mina, Uruá, Areão, Castália, and Macapá), mainly differentiated by geographical location and by settlement patterns, rather than technological variability (Simões 1981; Oliveira and Silveira 2016).

Today, shellmounds from the Mina tradition are known to be found in a large region that extends from the archipelago of Marajó to almost the Parnaiba River delta, as well in the Guyana (Evans and Meggers 1960; Simões 1981; Silveira and Schann 2005; Bandeira 2016), maybe reaching Venezuela (Meggers, *apud* Simões 1981: 78) and Caribe (Bel 2012). Such distribution, however, is not continuous and there are no records in Amapá or French Guiana. The sites occur in estuarine areas, along rivers and bays, as well as on islands, and are often surrounded by mangrove forests. Their dimensions vary: Porto da Mina site has 40 × 30 m at the base and reaches 4 m of height, while the Ponta das Pedras is 145 × 70 m at the base and stands 9 m tall. Mina ceramics are also starting to be found in other types of open-air sites, such as Jabuti, located further inland and where they are associated with anthropic dark earths (Silveira et al. 2011), and possibly Eva 2, a San Jacinto-like (Oyuela-Caycedo and Bonzani 2005) site located near the forested border of the coastal savannas of French Guiana (Bel 2012; Pagán-Jiménez et al. 2015).

The chronology of the Mina tradition extends from 5570 to 1245 BP, making it one of the longest and persistent cultural complexes (Fig. 2) in the continent (Simões 1981; Bandeira 2012). A common technological trait spanning the millennia is the constant presence of shell tempering, albeit with varying proportions. Firing appears to have been low temperature. Vessel surface is smooth and red slipping is frequently applied. Shapes are simple and open, with flat or slightly rounded bases and flat or round rims. Plastic decoration includes incision, coiling, and brushing (Simões 1981; Bandeira 2008).

The Mina tradition is recognized due to its antiquity and the huge spread of its technological characteristics on ceramics from Mid- to Late Holocene assemblages, such as the Alaka phase in Guyana and the Guará phase in the lower Xingu River. Taken together with the ceramics from Maranhão shellmounds, this makes it not only very ancient and long-lasting, but also wide-reaching in Eastern Amazonia, encompassing an area ranging from the Lower Amazon to the coast several hundred kilometers southeast and northwest of the mouth of the Amazon. However, the excessive attention given to the early age of Mina ceramics outshined the long-term history recorded in these contexts, which have only recently been approached by regional ceramic variability analyses (Bandeira 2009, 2016) and in the variation of settlement patterns (Silveira et al. 2011).

Bandeira (2008) presents the best description of a Mina tradition shellmound. The author divides its history in different cultural periods, stressing that ceramics of this kind are found in all of them. In the Bacanga shellmound, east of the mouth of the Amazon, Mina tradition may be found even before the beginning of shellmound construction, between 6600 and 5800 BP. This event is revealed by combustion structures composed by blocks of laterite disposed in a circular fashion, associated with charcoal, food remains, and ceramics that share few technological and morphological attributes with the Mina tradition, as they are thin and well fired and don't feature Mina's characteristic shell-tempered paste. The analysis of the vestiges collected in these basal layers points to a scenario in which the diet was not very dependent on aquatic resources and in which the presence of ceramic material is less dense than in relation to overlying strata (Bandeira 2009).

After that period, strata dated between 4800 and 1830 BP show significant technological changes marked by the start of the construction of the shellmound and contexts pointing to a wider utilization of resources, based on fishing and shellfish gathering, as well as significative increase in the quantity of ceramics, lithics, and bone remains. Vessel form becomes predominantly globular, with mouth diameters around 30 cm and some surface treatment, including smooth, brushed, simple, and parallel incised lines. Occupational strata are composed by lenses of shells of different species, associated with soils of varying colors. Besides ceramics, remains of

terrestrial and aquatic vertebrate bones, charcoal, laterite blocks, lithics, and ornaments are also found.

Mina tradition shellmounds also feature human burials with individuals in flexed position in right lateral decubitus, frequently accompanied by shells and ornaments. Just as in the pre-shellmound period, combustion structures and evidence of postholes are found (Simões 1981; Bandeira 2012).

Around 5000 years ago, various shellmounds were already occupied throughout the ECA: Bacanga (Maranhão), Porto da Mina, Ponta das Pedras and Uruá (Pará), and Barambina (Guyana) (Simões 1981; Williams 1981; Hoopes 1994; Bandeira 2012). Between 5000 and 2500 BP, after this initial phase of coastal occupation, different Mina tradition sites are formed both on the coast and further inland, while the ancient shellmounds of initial sequence were still being occupied (Bandeira 2009).

Mina phase ceramics are also associated with open-air non-mounded sites located further inland, such as Jabuti, who is found on high ground on an island at the west bank of the Caeté River, 36 km from the coast. Jabuti has anthropic dark earths with deposits ranging from 40 to 100 cm without signs of accumulation of shells, fishbones, or soil as in other Mina sites. There is a single date of 2900 BP for the early formation of this site (Silveira et al. 2011).

Above Mina phase occupations, ceramic fragments tempered with different materials are found on the surface of various shellmounds. These are associated with different occupations, including colonial Afro-Brazilian sites, but unfortunately not much is known about them (Simões 1981:14) Likewise, in Maranhão, two cultural assemblages were chronologically situated after the end of the Mina tradition at Bacanga site, the first associated with anthropic dark earths contexts and the most recent related to ceramics of the Tupinambá subtradition (Bandeira 2008, 2012) (Fig. 4).

Anthropic dark earth contexts associated with occupations above shellmound strata are common in all shellmounds studied in Maranhão. Such upper strata are 30–50 cm thick showing abundant ceramics, lithics, fish remains, human burials, and no shells and dating from 900 BP at Bacanga and Paço do Lumiar to 760 BP at Panaquatira (Bandeira 2012). These later ceramics are totally distinct from earlier Mina phase vessels, being similar to other Amazonian complexes such as the incised rim and Tupinambá traditions (Bandeira 2008, 2012). Such occupations persisted until the 1700s, after initial European settlement, and is associated with the Tupinambá Indians described historically (Bandeira 2016).

Shellmounds from Southwestern Amazonia (SWA)

The Monte Castelo shellmound is located on the floodplain of the Branco River (Fig. 5), next to the border of Bolivia and Brazil, and is currently 120 × 100 m long and 6.5 m tall. It had been previously excavated in the 1980s, and such previous research revealed that the shellmound is a monument built and occupied since the Early Holocene (Miller 2009, 2013).

Research at the site was restarted in July 2013 (Pugliese 2018). Excavations at MC have shown the presence of ceramics from the deepest strata to the surface of the site. The first samples of this technology were found in association with faunal and charcoal remains in occupational strata lacking shells as building material. There, an impressive volume of fragments of ceramic blocks and slabs were found, perhaps comparable to the clay balls found in Terminal Classic Maya sites in Central America or in the end of the Archaic period in the United States (Ford and Webb 1956; Gibson 2001). However, a few samples show walls or other attributes characteristic of pottery. The predominant temper is composed of quartz grains, which may have been added to the paste or might originate from a selection of a locally available sandy clay matrix for the production of these artifacts. Only a few diagnostic sherds were detected. Evidence of carbon soot on these pieces is rare and their use is still under investigation.

The strata that cover these initial occupations contain a larger investment in pottery making (Fig. 6). Likewise, the context in which these later ceramic materials are found differs notably

What do Amazonian Shellmounds Tell Us About the Long-Term Indigenous History of South America?, Fig. 4 Ceramics from coastal shellmounds in the state of Maranhão (Bandeira 2012): (**a**) Tupinambá, (**b**) associated with TPI, (**c**) Mina tradition, (**d**) pre-shellmound culture

from earlier strata. What before was composed by a matrix similar to an earthwork, in which structured features are not common, turns into a context in which intense domestic activities were recorded in firepits and other remains of food production and consumption. These horizontally overlaid strata, each about 10 cm thick, record a series of occupational contexts covering the initial occupation of the site. Stratum L is composed of a "floor" cut by negative features such as stake and postholes which seem to mirror the malacological contexts of strata K and M; the excavation of a

large hearth reached through several of these strata, and the material which were found suggests that a combustion area used for processing food existed on top of the shellmound for a long period. The use of *cauixi* (freshwater sponge spicules) tempering on clay found in these intermediary layers of the oldest strata (>5200 BP), together with a change in the structure of ceramic sherds,

shows that firing was better controlled, reaching higher temperatures. Besides the inclusion of *cauixi* and quartz, some shell temper is also found.

After ceramics had been present at the site for a period that may reach 3000 years, the Bacabal phase (Miller 2009, 2013) shows several technological innovations at Monte Castelo shellmound. These ceramics, which are deposited over the last strata associated with the massive accumulation of gastropod shells (Stratum F), are found in high density and in association with lithics and different kinds of botanical remains. Strata A–D, where Bacabal materials are found, also contain a significant amount of zooarchaeological remains, with a prominence not only of whole and fragmented gastropod shells but also turtle, cervid, rodent, reptile, and fish bones and some bivalve mollusk shells as well. These evidences not only suggest the consumption of these animals but also the use of skeleton parts for the preparation of utensils such as ornaments, points, needles, and hooks. There are also recurring burials marked with contours or agglomerations of shells and contain associated funerary paraphernalia.

Analyses of the ceramic material have revealed that these vessels were produced with a paste tempered primordially with spicules, mixed with fine sands. Some fragments in the older strata also present shells as temper. The homogeneous structure and hardness of the ceramics shows that high temperatures were achieved at firing. Pots were manufactured by coiling with the addition of modeled apliqués. Surfaces were smoothed with several different techniques that can be identified by the traces of soft (such as bamboo and gourd) or hard (such as pebbles, seeds, and shells) utensils. Polished samples are also found, but the most recurring types of surface treatment are slips and red slip.

Excision and incision were the most recurring types of plastic decoration used. Painted motifs are not to be found. On the other hand, plastic decorations are plentiful, with the most frequent type featuring motifs formed by zigzagging excisions, creating triangular areas filled by thin parallel incisions. This same motif is also found in decorations which are based on incise lines, in which the created areas are filled with dotted lines. Large, parallel, and straight excisions abound, as do different types of incision and dotted lines, as well as two kinds of brushed decoration (by corncob or corn ear). This surface treatment confirms the presence of maize (*Zea mays*) in this context dating about 4000 BP. Applied handles are commonly found, from the simplest varieties to the most stylized, including zoomorphic and anthropomorphic pieces. The pot shapes are simple, with plane to concave bases and rims with simple contours. Mouth diameter and the thickness of the walls indicate that the pots had a wide range of dimensions, from small serving pots to large cooking pots (Fig. 7).

This is an archaeological culture with dates reaching back more than four millennia, sharing elements with the first known ceramic complexes, notably in relation to settlement patterns that relate to the exploration of aquatic resources described in the Mina phase, the lower Xingu sites, and the Taperinha site. The zoned-hachured pattern of the decorative elements has been used by Miller (2009, 2013) to link these ceramics to processes of diffusion starting with Valdívia phase sites from coastal Ecuador, whose early dates go back to ca. 6400 BP (Zeidler 2003).

In Bolivia, shellmounds are a part of the earthwork landscapes of the Llanos de Mojos (Denevan 1964, 1966; Erickson 2006; Prümers 2012; Lombardo et al. 2013), but little specific information has so far been published. Recently, three sites located south of the flooded savannahs, near the municipality of Trinidad in the Beni River, were excavated. These sites are similar to Monte Castelo in terms of their implementation and stratigraphic matrix. However, they have much smaller dimensions, currently reaching only less than 2 m of height. Initial mound building seems to have started 10,000 years ago, as small mounds were built at the edge of the savannahs bordering the Mamoré River.

Just as in Monte Castelo, since the Middle Holocene, these sites witnessed a greater investment in construction and accumulation of shells as well as other technological novelties, such as ceramics (Fig. 8). Ceramics were found there with dates starting ca. 6000 BP, bearing similarities to the intermediary layers in Monte Castelo.

What do Amazonian Shellmounds Tell Us About the Long-Term Indigenous History of South America?, Fig. 7 Bacabal phase ceramics from the Monte Castelo shellmound: (**a**) zoomorphic and anthropomorphic representations; (**b**) excise and incise motifs; (**c**) brushed with corncobs and ears. (Photos Carlos Zimpel)

What do Amazonian Shellmounds Tell Us About the Long-Term Indigenous History of South America?, Fig. 8 Pottery from Isla del Tesoro, Llanos de Mojos, Bolivia (Lombardo et al. 2013): (**a**) Incised ceramic sherd, layer dates (6235 ± 62 BP); (**b**) ceramics from Late Holocene earthworkers

Occupations relating to the constructive period of the site extend to ca. 4000 BP, which begins the chronological hiatus which extends until 400 BP. These recent reoccupations also coincide with the reappearance of ceramics and faunistic remains, which were associated with the well-known Late Holocene Earthmover societies (Lombardo et al. 2013). There are also reports of sambaquis in the

northwestern Llanos, near the Rogoaguado lagoon (Echevarría 2008). Considered beside the (little) information available about those sites, paleoecological data (Brugger et al. 2016) indicates that they may also corroborate the pattern of association between ancient pottery and malacological material accumulation that is beginning to be recognized in the region's early settlements.

Shellmounds Landscape Formation

The monumental character of shellmounds is still unexplored in Amazonian archaeology, differently from what happens with this type of site in the southern and southeastern coasts of Brazil (Fish et al. 2013). The smooth topography of the areas where these sites were built in the Amazon highlights the constructed sites – which can surpass 6 m of height and have dozens of thousands of square meters in area – as imposing features of the local landscape. In the floodable savannahs of SWA, during some seasons, the shellmounds are the only features rising above the water in a radius of kilometers. The significance and persistence of these places must be considered under this perspective.

In the three areas of occurrence of known *sambaquis* in the Amazon, the same general structure in the stratigraphic composition (Fig. 9) – in simpler or more complex versions – seems to be visible from the available data, indicating parallels in their histories. The first settlements featured earth mounds dating to the Early Holocene that reach a maximum height of around 2 m, such as in the case of Monte Castelo. Subsequently, throughout the Middle Holocene, the sites undergo changes in their pattern of occupation, marked

What do Amazonian Shellmounds Tell Us About the Long-Term Indigenous History of South America?, Fig. 9 Synthetic stratigraphy from Amazonian shellmound profiles with available chronological information from calibrated radiocarbon dates (BP). I, Monte Castelo (Beta408413, Beta408414); II, Isla del Tesoro (Lombardo et al. 2013: Poz-34228, Poz-34229, Poz34230, Poz22902, Poz34232, Poz36136, Poz34301, Poz36135); III, Taperinha (Roosevelt 1995); IV, Porto da Mina (Canto Lopes 2016: Beta439361, Beta439362, Beta439363, Beta439364); V, Panaquatira (Bandeira 2012). * Estimated layer ages after Miller (2009, 2013), Roosevelt et al. (1991), and Roosevelt (1995)

by the use of massive accumulations of shells as a constructive material, forming thick layers that intercalate occupational structures and mounds, where the variability of vestiges is much more expressive. It can be considered that from this period on the sambaquis acquire a truly monumental character, standing out in the landscapes with proportions like no other sites in the basin.

During this period, an expressive increase in the species undergoing management occurs. This was archaeologically recorded mainly by the presence of new botanical remains on the sites, often carbonized and associated with combustion contexts. These changes are followed by a long period of continuity in this type of constructive activity, and the populations which carried it out also produced ceramics with more sophisticated technologies than those used by their predecessors. These contexts also present a wider variability of types of lithic and bone instruments. In fact, between 5000 and 4000 BP, the sambaquis are practically the only sites in the Amazon and in much of the continent where the production of ceramics is so systematically and expressively confirmed.

Taken together, these three facts (the construction of monuments, the appearance of new plants, and the development of more sophisticated technologies) seem to indicate that the changes observed in Amazonian shellmounds along the Middle Holocene are related to the transition from low-density landscape management to the beginning of a new indigenous history, which would culminate in the high-density landscape management which was later dispersed throughout the basin (Neves and Petersen 2006). When searching for historical meaning in the continuities and variations in settlement patterns recorded in structural changes in the shellmounds layers, we can also take into account a series of occurrences taking place further south in the continent, such as the construction and occupation of earthworks with malacological materials in the Paraguay River (Schmitz et al. 1998; Eremites De Oliveira 2003; Migliacio 2006; Schmitz et al. 2009). The construction of small shellmounds in the Ribeira do Iguape river valley since the Pleistocene transition is also noteworthy. Starting in the Middle Holocene, burials related to the known burial patterns of coastal shellmounds start appearing in these sites, followed by reoccupations of the region during the Late Holocene (Figuti et al. 2013). The explosive increase in dates for coastal shellmounds related to the period between 4000 and 2000 BP, 4ky after the first occurrences of this type of site (Gaspar et al. 2008), coincides with the construction of shell strata in Amazon sites, also founded in the Early Holocene and occupied until the present or the recent past. Other than the well-known Tupinambá reoccupations of the coastal sites, which may have been extinguished by the advancement of European colonization, dates in superior layers of shellmounds surpassing the first millennium of this era are common.

If we expand the limits of this approach, one could observe congruences between the contexts of emergence and development of shellmounds in the Amazon and in Colombia (Reichel-Domaltoff 1985), Venezuela (Cruxent and Rouse 1961), Panamá (Hoopes 1995), Southeastern United States (Sassaman 1993, 2004a, b), and in the Lower Mississippi Valley (Russo 1996; Sassaman 2004c), or even in various parts of the Pacific coast, where these sites occur from Chile to the United States. This is an enormous history contained in a long period of construction of shellmounds and associated landscapes in the continent.

Why Long-Term Indigenous History?

> L'intérêt de ces enquêtes pour l'enquête, c'est, au plus, d'accumuler des renseignements; encore ne seront-ils pas tous valables ipso facto pour des travaux futurs. Méfions-nous de l'art pour l'art.
> Braudel (1958)

The construction of a long-term history of the indigenous populations of the South American lowlands has been the object of archaeological research throughout the Amazon. Historical ecology approaches in particular have changed our understanding of the variability in the relation between mankind and the environment, adding to the understanding of how this took place in the long-term occupation of the continent. A lot

of this research has revolved around investigating the periods in which the most intense changes in the landscape are perceived archaeologically, proposing interpretations for the emergence and maintenance of cultural traits (Heckenberger 2005; Ballé and Erickson 2006; Thompson and Waggoner 2013).

The long-term indigenous history proposed here consists in the analysis of similarities and differences, continuities and changes in order to interpret the way in which the dialectic between the structures and events took place in the past, seeking to contribute to the understanding of the historical contexts in which they were produced and have been signified. To this end, the evaluation of whether an event is relevant in relation to long duration structures partially depends on the analysis of similarities and differences in the artifactual variability and on the archaeologist's ability to provide a plausible theory based on their internal perceptions, motivations, and cultural standards (Hodder 1987).

Archaeologically speaking, we can state that much of what can be observed in present-day cultures is the result of long-term history, which is represented in the present by the continuation of traits that appeared in remote times. In the Amazon, the persistence of certain cultural traits in artifactual assemblages and settlement patterns may represent the continuation of well-adapted lifestyles which were developed by the pioneer populations that colonized the region between the Late Pleistocene and the Middle Holocene (Neves and Petersen 2006) – not to be confused with a stagnation in time and place. In this sense, archaeological investigation of persistent places does not reject contemporary indigenous history. Rather, these studies should integrate themselves with it so that the places where long-term indigenous occupation can be archaeologically accessed may be researched ethically (Meskell 2005) and so that their results reach expected representativeness in the problematic political and social contexts in which they are carried out (e.g., Pugliese and Valle 2015). This stems from the recognition of the immeasurable worth of these sites for the construction of LIH and that the rights of indigenous people of these places must prevail over the territorial rights imposed by national states.

In relation to this, it is relevant to recall the potential archaeology has to change paradigms in contemporary communities. Archaeology must address the construction of scientific knowledge about the past, which aids our understanding of the present and which may substantiate the construction of a future in which human occupations not only contribute to the maintenance of biodiversity but also sustain a fairer and more diverse society. There is growing consensus among researchers that archaeology must take a central role in the investigations of the relationship between humans and the environment, building insights into wider issues, related, for instance, with the management of tropical forests (Ballé and Erickson 2006; Iriarte et al. 2016; Watling et al. 2015, 2017).

Furthermore, the absence of socially useful approaches to archaeology may lead to the disengagement of talented researchers, and maybe the very survival of the discipline is conditioned by its intellectual engagement with great challenges faced by present-day communities (Van der Leeuw and Redman 2002). In this sense, exploring the connections between the ethnographic present and the archaeological past in the search for a new ontology of the archaeological present (Hicks 2016) of the ancient occupations of the Americas allows knowledge to be used so that remaining meaningful places are respected and territories are kept in existence.

In fact, many of the most important archaeological sites in the Amazon are located in areas occupied and reoccupied throughout the millennia, which now house contemporary occupations, be they villages, towns, or even large cities. Unfortunately, it is still common to find the descendants of ancient inhabitants residing in the periphery of urban agglomerations, in situations of social risk, used as cheap labor to sustain local economies. In all such places, archaeology has the potential to create a foundation for the insubordination of traditional populations to the destructive drive of nation-states, if it can overcome its traditional colonial role to be

appropriated as an instrument in these peoples' struggle for sovereignty (McGuire 2004).

The Indigenous History of Middle Guaporé River Basin

Shared between Brazil and Bolivia, the basins of the Guaporé and Mamoré rivers are known as one of the regions with the highest linguistic variability in the planet. Over 50 indigenous languages have been found here, belonging to 7 families (Arawak, Chapacura, Jabuti, Nambikwara, Pano, Tacana, and Tupi), as well as 11 isolated languages (Aikanã, Canichana, Cayubaba, Iranxe, Itonama, Kanoê, Kwazá, Leko, Mosetén/Chimané, Movina, Yurakaré), sharing various lexical elements among them. For historical linguistics, this complex patchwork of oftentimes genetically distant languages in the present is probably a result of a number of waves of settlement in the region, whose descendants have been living together in the area for millennia (Crevels and van der Voort 2008).

The first pieces of written information referring to the occupation of the Guaporé were produced in the eighteenth century, in a context of dispute of this region between the Spanish and Portuguese empires. In the colonial period, the Guaporé was the fluvial connection between Villa Bella, in Mato Grosso, and Belém, in Pará, a route which gained importance at that time through commerce and capture of Indians. Portuguese and Spanish both claimed the river, trying to control the dense indigenous populations that inhabited the region concentrated in religious missions (Lucidio 2013). Next to the Branco River, missions and old colonial settlements were installed, and the information available about these places help us identify some of the indigenous occupations of the region in the eighteenth century (Fonseca 1874, 1881).

The first mission in the region, Santa Rosa, was founded by Spanish Jesuits in 1743 in an area on the right margin of the Guaporé where the Aricoroni, speakers of Chapacura, lived. In 1744, over 4000 members of the Moré indians, also Chapacura speakers, were subjugated in San Miguel, located on the river of the same name. San Simón was founded in 1746, in the Branco River, and around 700 people lived there between Morés and Mekéns, a part of the Tupari branch of the Tupi language family. The Mekéns are also mentioned as part of the population of the Portuguese settlements of Ilha Comprida (1742), located in the mouth of the River Mequéns, and Casa Redonda (1752), in the mouth of the Corumbiara River (cf. Fonseca 1749; Amado and Anzai 2006).

The decline in mining, the discovery of more efficient commercial routes, and the end of the territorial dispute between Portugal and Spain resulted in a diminished imperial interest in the Guaporé region. The people who inhabited its margins, who had been enslaved, killed, or concentrated in missions, could finally go back to living in relative freedom, and many of them headed up the river toward the head of the tributaries on the right margin, since following those on the left could mean encountering Jesuits in Bolivia (Lucidio 2013).

The Tupari linguistic family was rediscovered by Brazilian civil servants and ethnologists in the twentieth century (Snethlage 1937; Caspar 1953, 1957). It has four languages: (1) *Makurap*, centered around the head of the Branco River; (2) *Ayuru*, around the Colorado River; (3) *Mekéns*, around the Mequéns River; (4) and *Tupari*, in the heads of Machado River tributaries (Moore and Galucio 1994). When found in the twentieth century, speakers of Tupari shared a tragic history of contact with capitalism due to the rubber boom that spread throughout the entire Amazon, ravaging entire populations.

The first rubber plantations in the region were installed near the Branco River circa 1910, at a place known as Laranjal, where a Bolivian owner concentrated 600 individuals for rubber work (Snethlage 1937). Their exact identity is unclear, but in 1924, Aluízio Ferreira, who would become the governor of Rondônia in later years, took refuge in this area and described the presence of Makuraps there. He attests the same for the Paulo Saldanha plantation, near the head of the Branco River, founded by the Guaporé Rubber Co., which soon after would install the São Luiz plantation downstream.

These plantations were responsible for incorporating the Makurap, Ayuru, Jabuti, Arikapú, and Aruá into rubber exploitation work, as well as *poaia (Psychotria ipecacuanha)* and Brazil nut (*Bertholletia excelsa*) gathering. In 1927, a plantation employee accompanied by a retinue of Makurap visited the Tupari malocas (T.N.: indigenous Amazonian long house) in the headwaters of the Branco River, convincing these groups to work at Paulo Saldanha (Caspar 1953). The Tupari had heard of this new non-indigenous presence in the area due to reports by neighboring Makurap, who had acquired tools that the Tupari greatly valued after the contact. Soon, the plantations become a local hub, consequently spreading disease (Tupari 2013).

Caspar (1953) estimates that in the late 1920s, at least 3000 people inhabited the headwaters of the Branco River, due to a 1948 report by an elder relating the existence of at least 30 *malocas* in the area before contact with the rubber trade. In 1934, Emil Heinrich Snethlage was in the Branco, and before reaching the Tupari *malocas*, he visits the São Luis, reporting a complete absorption of indigenous labor in the plantation as well as cases of physical punishment suffered by the Tupari. Upon reaching the *malocas*, he only finds three of them, therefore estimating a population of 250 inhabitants (Snethlage 1937).

In 1948, Caspar lived among the Tupari where he notes the existence of temporary relations with the rubber trade when men moved temporarily to the São Luís plantation to work in exchange for manufactured products. At this time, they lived in two malocas, around 200 under the leadership of Waitó and Kuarumé, Caspar's interlocutors. According to a report by Konkwat Tupari, a daughter of Waitó Tupari, the Tupari people were forced by the plantation owner to leave their malocas and move indefinitely to the São Luiz in 1953. He also moved other families to the Laranjal plantation, preventing them from returning to their homes after working in the plantation (Fonseca 2008). Amnin Tupari describes Laranjal as a small town, formed by families, both Tupari and non-indigenous, involved in the production of foodstuffs to supply the great huts of the rubber plantation (Tupari 2013).

This moment of intense contact with the São Luis is crucial to the history of the Tupari. In 1954, a measles epidemic would irradiate from here, leaving the Tupari on the brink of extinction. In 1955, Franz Caspar visits the Branco River again and meets a group of refugees from this group, amounting to no more than 66 people living in a single *maloca,* probably in Laranjal (Caspar 1957).

Up until 1980, the plantations are sold between owners, many of whom kept Indians working in conditions tantamount to slavery. That year, the Branco River Indigenous Station is created in the old headquarters of the São Luis. Ethnologist Apoena Meireles works on freeing many people from this regime of slavery (Meireles 1983). Finally, in 1983, the Rio Branco Indigenous Reservation is demarcated. However, a few settlements were left outside its limits, including three of them, inhabited mostly by Tupari, inside the Guaporé Biological Reserve, demarcated the year before.

The Contemporary Indigenous History of Monte Castelo Shellmound

The migratory movement of the Tupari from northern Mato Grosso to the Rio Branco basin and the reoccupation of ancestral areas in the Guaporé River are known in the literature since the publication of Franz Caspar's ethnography in 1953. According to the Tupari, their ancestors reoccupied archaeological sites when they arrived in that region, a common practice when human settlements move. This is due to privileged characteristics of these places in their environment, such as the topographical advantages of wetlands "islands" or the fertile and fish-rich areas adjacent to fluvial terraces.

However, over the last two decades of the twentieth century, the populations that traditionally occupied the middle Guaporé underwent a moment of their history in which new displacements were needed due to the creation of various conservation units in the region. The demarcation of indigenous lands and establishment of federal and state reservations restricted their mobility and precluded their access from wide areas.

In the specific case of the Rio Branco Indigenous Land (RBIL), the demarcation process left

out central components in the history of occupation of that indigenous territory out of its limits. Like the Laranjal "island," the Palhal village, situated downstream of the RBIL, a very old settlement recognized for the worth of its fishing and agricultural lands, was left outside of the RBIL and inside the Guaporé Biological Reserve (Rebio Guaporé). The same fate befell the Monte Castelo shellmound, which was often used as a seasonal settlement, mainly for hunting and gathering activities in the wetlands during the dry season and for fishing and gathering during the wet season, and a strategic place in the route to Versailles, an Indigenous village in the Bolivian margin of Guaporé river, where the Tupari trade boats and forest resources. During the dry season, the site converts into a privileged spot for big game hunting, especially the cervids which populate the fields and the tapirs which inhabit the Branco's swamps at that time of the year. In addition, the site is part of a settlement system which encompasses literally all areas above the waterline during the wet season (locally called "islands"), places used as seasonal logistical camps, but also as cemeteries.

The current resistance to expropriation of the lower Branco River settlements, explicit in the continuing occupation of sites outside the RBIL, creates a case in which archaeological heritage can act on people's present, supporting a relationship of belonging not to be overwhelmed by Western territorial rights. Going beyond this case, this notion of archaeological heritage geared toward what these sites represent to the people who make use of it may be the most combative to the destruction caused by the advancement of national societies on traditionally occupied territories in the Amazon, if approached as an effective form of protection of places that hold significance to the present occupants of this area. Understood in its present subjectivity, this idea of archaeological heritage can contribute to the construction of a LIH that can be a tool for the transformation of the social relations which took hold with the advancement of capitalist society, helping to reclaim places with meaningful roles in the formation of past and present indigenous territories.

In this sense, the contemporary occupation of the Monte Castelo site constitutes an emblematic case for the construction of the long-term history of the indigenous populations of the Amazon based on shellmound archaeology. Right when we first took up research at the site, in 2013, we noticed the presence of recent remains, indicating that although the site was located inside a federal reserve, prohibiting the development of activities by local populations, it still received regular visits by hunters. Sometime later, when our presence was intensified with new excavations in 2014, signs which intentionally warned us about the ownership of this place started cropping up. Name of persons and villages started to be carved on trees, and there was an increase in the area of activity of the current occupation, previously centered on small clearings in the northern and southeastern summits of the site. During the 2016 excavations, besides new dates carved on trees, we found true signatures, with name and ethnic affiliation. These signs seemed to be strong acts of demarcation, a reaction to the invasion of a meaningful place (Fig. 10).

However, our attempts to enter into direct contact with the Indians, heading toward their villages by land and water, had come to no fruition. Nowadays, after the shellmound was isolated by the demarcation of the reserve and their traditional occupations were restricted to ILs and maroon areas, access between the site and the upper Branco River is practically impossible during most of the year. The drastic reduction in circulation of boats allowed hydrophilic vegetation to take over the area between the shellmound and the nearest village, Palhal, and the herds of buffalo which multiplied with the extinction of nearby farms have made the overland route truly deadly. Despite this, the inhabitants of the Rio Branco IL, who never truly abandoned their settlements outside the IL, continue to use the shellmound, but mainly in periods of extreme flood, when it is possible to overtake the vegetation coverage, which becomes a little less dense during this period, allowing fluvial paths to be made.

Paradoxically, the indigenous population has been growing over the past few years due to the protection granted by the demarcation, but

What do Amazonian Shellmounds Tell Us About the Long-Term Indigenous History of South America?, Fig. 10 Site's current occupation signs (**b**–**d**) and activity areas (**a**, **e**). (Photos by Francisco Pugliese)

productive areas inside the RBIL are not plentiful. The exhaustion of resources in the most explored parts of the IL have forced an intensification of use of external areas and a growing movement to reclaim places inside the ReBio Guaporé which were traditionally occupied. Furthermore, isolated populations from the Massaco IL, located on the left margin of the Branco River, have been approaching the southern villages of the Rio Branco IL, and they were even seen by inhabitants in some recent cases, increasing the pressure on them and making exploration of the surroundings of some villages very dangerous.

Contact with the inhabitants of the RBIL was finally established in October 2016 when we sailed downstream from nearby villages into the IL and met the people who communicated with us in the shellmound's trees. At that time, we were introduced to the territorial claims of the various communities we visited, and collaborative projects were proposed to us, mainly aiming to reclaim Monte Castelo and others sites in lower

Branco River for their land. The archaeological project in the shellmound and other sites, all places of ancestral indigenous occupations, is producing data that must be used to repatriate these places to modern indigenous people. In relation to this, even if linguistics and the relatively recent character of the current occupation of the villages of the Rio Branco IL may allow for questioning the phylogenetic relation between its inhabitants and the people who produced the archaeological packets of the shellmound, the return to the region of middle Guaporé River is described by the local elders as a return to a land that had already been occupied by ancestors, and that was the reason why they chose the Branco River in their last migration. Currently, these populations consistently occupy this place in a similar manner to how their predecessor occupied it (even producing analogous contexts of activity). The indigenous history of the region, associated with the meanings held by that place, makes the shellmound landscape a fundamental component of their territoriality.

It is important to remember that the search for correlations between the history of occupation of the archaeological sites and current indigenous occupations must consider the multiethnic and multilinguistic pattern that became predominant in various parts of the Amazon from, at least, the tenth century on. If on the one hand this pattern complicates the establishment of strict correlations between the past of an ethnicity and the material culture of the sites, because the degree of resolution which can be obtained from the archaeological record only allows for direct correspondences to be observed in specific contexts (Neves 2011), on the other, the case of Monte Castelo demonstrates that for the archaeology of persistent places, this search for strict correlations is not the way to understand its territorial characters. What we propose here, based on the case of the indigenous occupation of the Guaporé wetlands, is that shellmounds are fundamental for the long-term history of occupation of the region where they are implemented, and, in this way, they are a part of the formation of all indigenous territories who have embraced them, independently of the identity which might be conferred to the archaeological record (Meskell 2001).

The Long-Term Indigenous History of Shellmounds in the Amazon

For millennia, monumental sites all over the world have shaped landscapes which reflect histories of colonization, diffusion, and migration which connect communities in faraway regions and through countless generations. Long continuities are frequent in these places, and some characteristics of these occupations persist, transcending the hiatuses which commonly exist in these sites' chronologies, denoting the permanence of structural traits in its history (Sassaman 2005).

In the Amazon, the advance of shellmound research has demonstrated covariations between chronology (Fig. 2), ceramic technology, and settlement patterns which are related to the history of occupation of a very wide region, which encompasses three known areas of occurrence. In these places, characteristics which can be considered structural in the human occupations which produced the sites present shared elements, and related events can be accessed through the archaeological record (e.g., changes between constructive and occupational layers), pointing to a common history. The structure of this history appears in the sequence of periods of occupation of the sites, which was shaped by recurrences in relation to the emergence and complexification of ceramic technology, to the morphology of stratigraphic layers, and to the distribution of remains in the sites in the Middle Holocene, as well as by the reoccupations of these places during the Late Holocene.

Some elements shared by the pottery, such as the use of sand and shell tempers in older technologies, seem to indicate that the relative synchronic appearance of ceramic assemblages in several sites was derived from a process of cultural diffusion; nevertheless, the change in the artifacts from modeled to coiled technologies marks a scenario of intense cultural change starting in the Middle Holocene. The contexts where these changes are

recorded, with high variability in plant and animal use remains, may be related to the development of a productive model based on agroecological diversity, a pattern dispersed throughout the Amazon in very ancient times and that can still be found today (Neves 2011).

In the search of a LIH of the Amazon based on shellmound archaeology, the Monte Castelo site constitutes a privileged chronological record for the recognition of persistence and innovations, notably in relation to the presence of dates distributed from the end of the Early Holocene to the thirteenth century (Miller 2009, 2013). The site is inserted in the southwestern Amazonian regional context, in which the exceptional language dispersion patterns of the past may be associated with patterns found in archaeological sites (Neves 2011). The recognition of these patterns may contribute to construct a new perspective on the archaeology of Amazonian shellmounds and about the appropriation of these places by present-day communities.

It is important to highlight that in other parts of the globe, shellmounds are archaeologically identified as aboriginal ancestral sites (Australia, Ulm 2013), monuments from ancient indigenous complex societies (Southeastern North America, Sassaman 2004c), or even as historical references for the construction of modern national identities (Japan, Mizoguchi 2004). In California, the indigenous history of shellmounds of the San Francisco bay area has been investigated by archaeology since the very beginning of the twentieth century (Uhle 1907; Nelson 1909). Today, they are considered sacred places with a history charged with meanings in mythology, and the indigenous movements are using archaeology to support the reclaim of these sites as part of their ancestral territories. On the other hand, in the Amazon, shellmounds were never approached by archaeology in a similar vein. Paradoxically, if on the one hand the region hosts one of the largest extensions of officially recognized indigenous territories in the world, on the other, the debate about the antiquity of its chronology has hindered attempts to approach ancient sites as persistent and meaningful places for current communities. Together with sites along the margins of rapids, big waterfalls, and the meeting of the main tributaries of the basin, Amazonian shellmounds are part of landscapes which have been built and reoccupied for millennia, and they must be explored in relation to the true spatial and temporal reach of their archaeology.

This is of special relevance for this chapter's objectives, since the three areas of shellmound occurrence in the Amazon are located in old indigenous territories, now severely changed by recent colonization processes in the Amazon. In the EAC, extractivist mining of malacological lime deposits has partially or completely destroyed many shellmounds, and the advance of urban perimeters has intensified the modification of the landscapes to which these sites belonged, to the point that today many of them have completely disappeared. In the SWA, true massacres of indigenous peoples occurred in the second-half of the twentieth century, and the expansion of the agricultural frontier still is, without a doubt, the current biggest problem for the conservation of the sites. If the creation of various conservation units in the middle Guaporé River basin insulated important areas from this process, they also restricted local communities from accessing various features of their territories, leading to an unnecessary and harmful opposition between conservation and traditional occupation of these places. In the LA, the Taperinha site has been partially destroyed by shell mining, and many sites recorded in the nineteenth century may never be found again for the same reason. However, the most extreme deterioration of indigenous territories in the region can be found is the lower Xingu River. The construction of the Belo Monte dam and other associated developments have set loose a true cataclysm in the region. The local shellmounds are located only a few kilometers downriver from the Xingu's "Big Turn," where the dam's axis was dramatically erected. In some of these areas, initiatives for the protection and recovery of these places have been put into place by indigenous people and other traditional communities, similarly to how the inhabitants of the Rio Branco Indigenous Land currently relate to Monte Castelo. The results of archaeological research should be used to support the recovery

of meaningful components of the deep indigenous history of the continent.

Final Remarks: Shellmounds and Ceramics in Amazon

Recently obtained dates from Monte Castelo shellmound confirm that ceramic remains found on its basal layers are related to occupations dating before 5200 BP, an assertion which is also supported by Miller's (2009) dates for these layers, reaching 8000 BP. This implies that the ceramic assemblages found in these layers have the same age of the earlier ceramics of the Americas, resulting in a new interpretation about these ancient contexts. However, differently from what has been observed in sites like San Jacinto 1 (Oyuela-Caycedo and Bonzani 2005), for instance, ancient ceramics from Amazonian shellmounds present evident stratigraphic correlation with contexts of food processing, being artifacts used for the ordinary preparation and consumption of food. The analysis of residues and other types of microremains will assess this hypothesis, but early Amazonian ceramics are also distinct from the typically highly decorated ancient ceramics found elsewhere in South America. In Amazonian shellmounds, ceramics characterized by intense decoration normally appear in more recent contexts (Betancourt 2013; Zimpel and Pugliese 2016), from the Middle Holocene on, and, in some cases, in layers covering older occupations, which present a simpler ceramic technology coupled, like in Monte Castelo, with a high density of remains.

Despite the lack of a correlation between the emergence of ceramics and the advent of agriculture in the lowlands of South America (Neves 2016), data about the first vestiges of this technology in the continent reveal an association with food processing and consumption. Roosevelt (1992) reports proposed a culinary use in the oldest ceramics in Taperinha, but she relates its use to a diet specialized in fish and mollusks, where there is no use of plants such as corn (1999). What Monte Castelo has demonstrated is that, moving beyond the debate about whether societies specialized in fishing, hunting, and gathering adopted agriculture or not, dietary patterns among early ceramists already leaned toward generalism. As has been observed in a series of Early-to-Middle Holocene sites in various parts of South America (Dillehay 2008), diet diversification was also the choice of most Amazonian settlers (Roosevelt et al. 1996), even with the precocious presence of various plants which would become important for the emergence of agriculture elsewhere in the continent. Such generalist strategies are also characteristic of early ceramic technologies associated with food-processing remains.

The chronological correlation (Figs. 2 and 9) between innovations observed in the ceramic assemblages of the Middle Holocene suggests that their emergence is related to structural changes in LIH (sensu Sassaman 2004b, c, 2005), which seem to be a good alternative hypothesis to explain artifactual variability without relating it exclusively to processes connected to the emergence and diffusion of early ceramic technologies. This is because that assumption is invalidated by the chronology verified in Amazonian sites where the most ancient ceramics were actually found, like Taperinha and Monte Castelo. A deeper understanding of historical contexts of the tropical lowlands around 8000 BP is fundamental to appropriately pose better questions about the advent of ceramic technologies and to test the origin hypotheses. Hypotheses relating to the emergence of ceramic technology should focus on the same chronological framework, be they based on diffusionist or multiple origin hypotheses and novelties in artifactual variability in Middle Holocene assemblages addressed by more specific regional investigations, such as those involving ethnogenetic processes.

Acknowledgments We would like to thank all the people that helped in the development of the archaeological research in the middle Guaporé River basin, especially the amazing team of the Laboratory for Tropical Archaeology from the Museum of Archaeology and Ethnology of São Paulo University and the people from government agencies (Funai, ICMBio, Idaron) who gave us crucial

assistance to carry out the fieldworks. The Laboratory for Geochronology of Brasilia University hosted the analysis of early ceramic materials from Monte Castelo and we have a special thanks for the support of Dr. Roberto Ventura Santos. The pictures from Dr. Elisangela Oliveira of Taperinha ceramics brought new colors to the discussion, so we want to thank her and Museu Paraense Emilio Goeldi's crew for giving us the rights to use the images. Diogo Lima Saraiva from Brasilia University was responsible for the translation from Portuguese to English. Postdoctoral fellowship 152582/2018-5 from CNPq - Brazil (FAP), PhD fellowships from Capes (FAP) and CNPq - Brazil (CAZN), and other grants from NGS and CNPq - Brazil (EGN) funded this research. Communities from the municipality of Costa Marques to the Rio Branco IL have kindly hosted us in their lands and helped us in so many ways, and this chapter is dedicated to them.

Ambrosetti, Juan Bautista

Javier Nastri
CONICET, Depto. de Cs. Nat. y Antropológicas + Fundación Azara, Universidad Maimónides/ Universidad de Buenos Aires, Buenos Aires, CABA, Argentina

Basic Biographical Information

Considered the "father" of Argentine archeology, Ambrosetti was born in 1865 in Gualeguay, Entre Rios Province, but lived most of his life in Buenos Aires. He initially became interested in natural sciences, interacting very young with eminent naturalists Eduardo Holmberg, Florentino Ameghino, and Pedro B. Scalabrini. At the age of 20, he visited indigenous reductions in Santa Fe Province and overturned this experience in a first book entitled *Viaje de un maturrango*, published in 1893 and signed with the pseudonym Tomas Bathata. There he expressed a strong criticism about progress and modern society, in line with the relativistic thinking of his teacher Scalabrini.

Between 1885 and 1891, he lived in the city of Paraná, where he held the positions of Head at the Section of Zoology at Natural Sciences Museum, President of the Library, and Secretary of the Police Department. Once he moved back to Buenos Aires, he undertook expeditions to Misiones Province and the Pampa, supported by La Plata Museum and the Argentine Geographic Institute. From the moment he was commissioned to explore the Argentine Northwest in 1895, archeology became his main interest (Cáceres Freyre 1967).

In 1903 he became the substitute professor of American Archaeology in the Faculty of Arts at the University of Buenos Aires, where he founded the following year the Ethnographic Museum that bears his name today. He remained as director until his death in 1917. During his last years of life, Ambrosetti was also an active participant at international conferences, especially the Congress of Americanists (Cáceres Freyre 1967). Some colleagues used to refer to him as "our national archeologist" given the active role played along these instances.

Major Achievements

Ambrosetti's contributions on Carahuasi rock art cave, the ruins of Quilmes, and Tafi menhirs are remarkable. He was, along with Adan Quiroga, the initiator of the research field called "Calchaquí studies." His *Notes on Calchaquí Archaeology* (Ambrosetti 1899) are a good example of the so-called philological-historical approach to archeological matters (Haber 1995). Focused on symbolic interpretation, it bears traits in common with contemporary developments in American anthropological archeology. In fact Ambrosetti was highly interested on similarities among the Pueblo Indians and Calchaquí populations, as pointed out earlier by the Dutch anthropologist Ten Kate, participant of Cushing's expeditions to the American Southwest.

To this first stage in Ambrosetti's production belongs *The Ancient City of Quilmes* (Fig. 1) (Ambrosetti 1897), his most accomplished work of interpretation that was not devoted to symbolism but to the functionality of the stone buildings of one of the most visited sites in Argentina today. Ambrosetti described the ruins with an unprecedented level of detail in Argentine archeology – counting with the support of the illustrations by Federico Voltmer – and was able to successfully define the shape of the calchaquí house, now known for this reason as "Ambrosetti house" (Fig. 2). He used historical data from the time of the Spanish conquest to provide a plausible working model of the bigger and most complex

Calchaquí settlement, located at the center of Santa María Valley, Tucumán Province.

In the early twentieth century, his work shifted to a more descriptive approach, probably along with the lines spread by Flinders Petrie and Max Uhle (Nastri 2010). In this vein, he published a rigorous study of pre-Columbian metallurgy (Ambrosetti 1904) and the first extensive monograph of an archeological excavation in northwestern Argentina (Fig. 3), in which contexts and findings were presented in detail (Ambrosetti 1906). The analysis of the materials recovered from this site allowed him to build the second chronological statement based on contextual data in the Argentine medium, identifying a *Calchaquí* component superimposed on the remains of a culture which he called "inferior" at the site of Pampa Grande (Salta Province).

Ambrosetti's masterpiece is the monumental *Archaeological Explorations at the Prehistoric City of La Paya* (Ambrosetti 1907), where he presented the contents of hundreds of burials from Inca and earlier times. This detailed evidence soon allowed Max Uhle to establish a first relative chronology of aboriginal times in northwestern Argentina (Nastri 2010).

On the whole, Ambrosetti's work at the Ethnographic Museum of the University of Buenos Aires contributed to position archeology in the field of humanities, while its innovative actions on archeological sites laid the foundation for the vigorous Argentinean tradition of field research to this day.

American Academy in Rome

T. Corey Brennan
Department of Classics, Rutgers University-New Brunswick, New Brunswick, NJ, USA

Basic Information

The American Academy in Rome, founded in 1894 and chartered by the US Congress in 1905 and 1912, is an independent center for the development of US artists and scholars. Its present institutional form dates to 1914, when the American Academy, newly consolidated with the American School of Classical Studies in Rome (founded in 1895 under the auspices of the Archaeological Institute of America), took up a joint campus on the Janiculum Hill, encompassing 11 acres.

The Academy still operates under its 1912 charter as "an institution for the study and practice of the fine arts and for the study and investigation of the archaeology, literature, and history of the Classical and later periods." The Academy appoints its "Rome Prize" Fellows through a juried competition (with now typically four out of an annual total of c. 30 fellowships reserved for ancient studies). In addition to a small staff (which includes a Professor-in-Charge for the humanities), a complement of residents (appointed by the Academy's Director), affiliated fellows, and visiting scholars and artists presently fill out the Academy community each year.

Major Impact

The Academy's most significant contribution to archaeology is the five decades (1947–1999) of excavation it organized at the site of the Latin colony of Cosa in southwestern Tuscany, tracing developments in the town and its territory from the important era of growth in the second century BCE through the early and later imperial and then Medieval periods. More generally, the Academy can be credited for the field training of many American archaeologists at Cosa and other more loosely sponsored digs in Rome and Italy, as well as through various summer programs it has offered.

By the time of the physical merger of the American Academy and American School on Rome's Janiculum in 1914, the School had a substantial library, an archaeological museum (principally assembled by Richard Norton, its Director from 1899 to 1907) and cast collection, a $100,000 endowment, and continuing

subscriptions from a number of foundations and colleges. It also had admitted women members since the turn of the century. However, the consolidated American Academy, now organized into two schools ("Fine Arts" and "Classical Studies"), would see women as full Fellows only in the Classics and Archaeology fields until the post-World War II period.

The pivotal year 1914 opened with Albert William Van Buren (American School Fellow in 1906) as Professor of Archaeology and in charge of the library. In that same year, the death of Thomas Spencer Jerome (US Consul on Capri) brought an important endowment jointly to the Academy and University of Michigan for a lecture series on Roman topics that bears his name. A journal, *Memoirs of the American Academy in Rome*, began in 1915, with a *Papers and Monographs* series soon to follow in 1919. In the period between the two Wars, Van Buren closely supervised an archaeologically based course of study for the Classical Fellows and shorter-term visiting students that included intensive explorations in Rome and travel in Latium, Campania, and Greece. (Links between the new Rome Academy and the American School of Classical Studies at Athens, which date to 1881, were close from the start.) A Classical Summer School was founded in 1923 that condensed the curriculum for Rome and environs for the benefit of American teachers of classics.

The disruptions caused by World War II led to the shutting of the Academy from 1940 to 1945. By that time, the institution had firmly established itself as a premier archaeological training ground for future American academics and museum curators. The Academy's impact here can perhaps best be seen in the significant number of both its scholars and artists who played a prominent role in forming and serving in the military Monuments, Fine Arts, and Archives (MFA&A) section that proved highly effective in preserving cultural properties in Europe during and immediately following the Second World War. The Academy also opened its properties in 1945 and 1946 for "leave courses" in archaeology and other subjects to military personnel and members of the US Embassy in Rome.

During the war years, the Academy's Trustees decided that it would henceforth broaden the institution's humanistic fields to encompass Medieval and Renaissance studies and (apparently with a view toward reducing overhead) discontinue the system of courses in both the Schools of Fine Arts and Classical Studies. These were significant choices that proved decisive for the Academy's present identity as a center for independent study and advanced research. Other measures included a revitalization of the Jerome Lectures and energetic participation in the new (1946) International Union of the Academies in Rome and International Association of Classical Archaeology (AIAC). The creation of the Fulbright Program in 1946 soon enabled the Academy to introduce two Italian scholars per year into the community, many of them archaeologists. One of the most important dividends of the "internationalization" of the postwar Academy was German photographer Ernest Nash's establishment there in 1957 of the Fototeca Unione archive, which remains a vital center of visual documentation on Roman architecture and topography.

Already in 1944, the Academy's Trustees had started discussions about finding a working excavation site once peace was restored in Italy. In 1947, former Fellow (and Yale University faculty member) Frank E. Brown returned to the freshly reopened Academy as Professor-in-Charge and Director of Excavations. Brown moved quickly to systematize and prune the Academy's museum holdings and to identify Cosa as the most promising site for an institutional dig. Excavations started at Cosa in 1948, and work continued (under Brown for almost three decades, followed by Russell T. Scott, and then Elizabeth Fentress) at regular intervals until 1999 with a series of publications that is still ongoing. The Academy also constructed a small museum on the site (1964–1968), which it turned over to the Italian government in 1981 when it was fully furnished. The research methods and results from especially the early years of work at Cosa have done much to stimulate work in Republican urban archaeology elsewhere in Italy, most directly Fregellae, and provided valuable comparanda for other sites,

including the situation of Republican Rome itself. Excavations that followed up the Academy's work resumed at Cosa under Russell T. Scott in 2013.

The postwar years saw the Academy make repeated attempts to expand its public acceptance in the United States and to increase revenues for its ambitious programs, including the Cosa excavations. Financial pressures led to the creation of a full-time paid Executive President based in New York starting in 1969. But one of many welcome developments was the decision in 1973 by the Andrew W. Mellon Foundation to endow the position of Professor-in-Charge, with Frank Brown as the first incumbent (1974–1976).

Though the central organization of the sustained work at Cosa as a multiyear institutional project has so far proved unique, the Academy has sponsored numerous other excavations at varying levels. These range from work in Rome by Frank Brown on the Regia (1964–1966), Russell T. Scott in the Area Sacra of Vesta (1987–1996), and Eric Hostetter on the northeast slope of the Palatine hill (1989–1995) to formal patronage of a large-scale University of Michigan excavation at Gabii in Italy conducted by Nicola Terrenato (2008–present), the Porta Stabia excavations at Pompeii (Steven Ellis, University of Cincinnati) and the Contrada Agnese at Morgantina (Alex Walthall, University of Texas). The American Academy also has established a series of summer programs on the analogy of its long-standing Classical Summer School, ranging from immersive experiences in general archaeology (annually from 1991 to 2012) and Roman pottery (first in 2006) to a series of rotating skills courses including epigraphy, ancient building documentation, and digital finds analysis. An effort of some 25 years to reorganize and properly catalogue the Academy's museum holdings has resulted in the creation of a new (2008) archaeological repository and seminar room dedicated to Richard Norton and A. W. Van Buren and a new archive for its excavation documentation, including the Cosa and Regia excavations, much of which is also available online at the Academy's website (aarome.org).

Notable past Fellows of the American Academy and its predecessor the American School who have made significant contributions in Mediterranean archaeology include Charles Rufus Morey (completing his Fellowship in 1903), Esther Boise Van Deman (1909), Charles Densmore Curtis (1915), Lily Ross Taylor (1920), Charles Alexander Robinson (1926), Howard Comfort (1929), James Henry Oliver (1930), Frank E. Brown (1933), Lucy Shoe Merritt (1937), Lawrence Richardson, Jr. (1950), Emeline H. Richardson (1952), William L. MacDonald (1956), Michael Jameson (1959), R. Ross Holloway (1960), Maria Teresa Moevs (1964), James Packer (1964), Susan Downey (1965), Russell T. Scott (1966), Malcolm Bell III (1970), Joseph Carter (1971), Eric Hostetter (1983), Ingrid Edlund-Berry (1984), and C. Brian Rose (1992), among many others. Archaeologists have often filled the rotating post of Professor-in-Charge, most recently Elizabeth Fentress (1996–1999), Archer Martin (1999–2001), and 2006 Fellow Kimberly Bowes (2012–2014, then serving as Academy Director into 2017).

American Anthropological Association (AAA) and Ethics

Janet E. Levy[1] and Morag M. Kersel[2]
[1]Department of Anthropology (emerita), University of North Carolina at Charlotte, Charlotte, NC, USA
[2]DePaul University, Chicago, IL, USA

Introduction

The American Anthropological Association (AAA), established in 1902 and currently with over 10,000 members, has a long and conflicted history of professional ethics. Originally comprised mainly of academic anthropologists, the organization now features members with employment both inside and outside of the academy. Anthropologists today can be found in the classroom, the boardroom examining organizational behavior, in a hospital room observing practitioners, or at a construction site assessing the significance of archaeology. Anthropologists undertake a particularly wide array of research methods, from physical measurements and blood draws by biological anthropologists to ethnographic interviewing and participant observation by cultural anthropologists, to the collection of artifacts and oral histories by archaeologists, and more. As a result, anthropologists encounter wide-ranging instances of ethical dilemmas and debates.

Key Issues

Since its founding, the AAA has grappled with what it means to be an ethical anthropologist, with significant debates on the subject continuing (Fluehr-Lobban 2003). In the AAA Code of Ethics (2009), the emphasis was on a "primary ethical obligation" to the "people, species, and materials they study and to the people with whom they work." This statement was congruent with the description of an anthropologist's primary obligation going back to the first comprehensive statement about ethics established by the AAA in 1971. Other responsibilities are to colleagues, students, employers, and to scholarship itself. The Principles of Professional Responsibility (PPR) established in 2012 state: "A primary ethical obligation shared by anthropologists is to do no harm" (available in AAA 2017). At the same time, the 2012 version emphasizes the complexity, fluidity, and potential internal conflicts of competing ethical considerations to be found in anthropological work. Because of the multiple ethical mandates with which anthropologists must engage, the AAA Code of Ethics attempts to provide suggested guidelines for best practice but rarely provides easy answers. The most recent version utilizes the capacities of the Internet to provide ongoing commentary, debate, and examples through lively blog exchanges and other means.

Development of the AAA Code of Ethics was not an immediate priority for the organization. In fact, the first formal code of ethics passed by an anthropological group was enacted in 1948 by the Society for Applied Anthropology. The concept of applied anthropology itself has engendered its own set of debates. In 1971 the AAA issued the Principles of Professional Responsibility, and in 1998, after much contentious discussion, a formal AAA Code of Ethics replaced this. That document was revised in 2009, resulting in a more nuanced version that is purposefully ambiguous on questions of classified research, leaving it up to the individual anthropologist to interpret. Intense deliberation over the AAA Code of Ethics continued for several years – this ongoing debate was prompted in part by highly publicized programs, like the Human Terrain System (HTS) in which some anthropologists have worked for the US military in Afghanistan and Iraq. At the same time, there are growing numbers of scholars who have started doing proprietary research for public and private companies and institutions, another contentious ethical topic for the AAA. Central issues for anthropologists engaging in these types of action are those of transparency, consent, conflicting obligations (toward funders, employers, the AAA, etc.), and the dissemination of the research outcomes. The most current code,

the 2012 Principles of Professional Responsibility, focuses on these issues.

Historically, conversations surrounding ethical issues within the AAA have been reactive rather than proactive, generated by moments of crisis like Vietnam, Cambodia, Project Camelot (the 1964–1965 US Army project to assess the sources of insurgency in Latin America using knowledge gained from anthropologists and other social scientists), and, most recently, the US Army's Human Terrain System and the potential destruction of the archaeological record during uprisings in Egypt, Libya, Qatar, Syria, and the Yemen. Changes to the code in the 1990s were intended to address earlier failings, but events in Iraq and Afghanistan in the mid-2000s renewed calls for a more active policy on ethics. Throughout the AAA's debate on ethics, critics have charged that the association has been too slow to respond to critical issues and that it has been unwilling to maintain a process for repudiating actions judged unethical. While a sanctioning process was established in 1971, it proved unworkable and was ended in the mid-1990s (Levy 2009).

Former chair of the AAA Committee on Ethics, Janet Levy, has suggested that earlier iterations of the ethical code provided no real guidance or direction for archaeologists and/or biological anthropologists to deal with issues such as the destruction of archaeological resources, the international trade in antiquities, or the bushmeat trade in nonhuman primates. For many years, ethics work by the AAA focused entirely on issues of cultural/linguistic anthropologists; the four-field nature of anthropology was not captured in ethics debates (Levy 1994). Since 1998, there have been limited attempts to speak to the issues encountered by archaeologists and biological anthropologists in the AAA's ethical statements.

Anthropological archaeologists have duties to systematically excavate, analyze, and report on the archaeological record while collaborating with the local communities and governments where they work. There are overarching issues of control over the production of archaeological knowledge, custodianship of cultural heritage, the legacy of colonialism, and ongoing requests for the repatriation of artifacts and remains (Bruchac et al. 2010). The Native American Graves Protection and Repatriation Act of 1990 (and its recent amendments) was passed to address the rights of lineal descendants, Indian tribes, and Native Hawaiian organizations to Native American cultural items, including human remains, funerary objects, sacred objects, and objects of cultural patrimony. This has encouraged both archaeologists and museums to reevaluate their practices in relation to Native American materials.

The relationship of archaeologists with the military also raises difficult issues. In 1919, Franz Boas, one of the founding members of the AAA, was censured by the organization for his critique in *The Nation* of anthropologists (including archaeologists) who acted as informants (spies) during WWI. Recently archaeologists who work with the military to protect archaeological sites in Iraq, Afghanistan, and Syria have faced condemnation by some anthropological colleagues for collusion and for implied support for military intervention. As it currently states, the AAA's Principles of Professional Responsibility (2012) are intended to provide anthropologists with the tools needed to engage in the development and maintenance of an ethical framework, especially when faced with conflicting ethical obligations. Critics find the wording overly vague and not appropriately prescriptive.

The current PPR, while briefly incorporating mention of specifically archaeological issues (such as site protection), retains the historic AAA focus on relationships among people. However, this remains useful for archaeologists, especially as archaeological practice turns toward more collaborative and community-oriented projects, which involve the same complex human relationships as cultural anthropology (e.g., Little and Shackel 2007; Silliman 2008). Recognizing that issues related to cultural heritage are a persistent and an increasingly important element of anthropology, in 2013 the AAA empaneled the Task Force on Cultural Heritage to produce a series of recommendations, which would allow the organization to take a more proactive rather than reactive stance on

threats to cultural heritage (broadly defined to include tangible and intangible aspects). The task force's goal was to increase appreciation of cultural heritage issues in anthropological discourse and to assist the AAA Executive Board in developing effective positions and practices on cultural heritage issues in the USA and internationally. In response to the recommendations made by the Task Force in July 2016, the AAA Executive Board released a statement on *Cultural Heritage Principles and Values* (American Anthropological Association 2016), which includes some guiding principles and best practices for AAA members related to cultural heritage.

At best ethics in anthropology are situational and often contradictory. Arriving at a code of ethics for the practice of anthropology is a long, negotiated, ongoing process, which is greatly enhanced by education and the recognition that there are complex conversations involving the various scenarios that anthropologists from all areas of the discipline face. Just as there are often no truly right and wrong answers, anthropologists can in no way consider codes of ethics the last word on ethical practice. All ethical debates are ongoing projects.

American Association of Physical Anthropologists (AAPA)

Michael A. Little
Binghamton University, SUNY, New York, NY, USA

Basic Information

The American Association of Physical Anthropologists (AAPA) was founded in 1930 after being proposed to and supported by Section H (Anthropology) of the American Association for the Advancement of Science (AAAS) in 1928. Aleš Hrdlička was the principle driving force behind the founding of the AAPA, also having launched the *American Journal of Physical Anthropology* (*AJPA*) in 1918. Hrdlička served as the first editor of the journal (1918–1942) and the first President of the AAPA (1930–1931). An early history of the AAPA in Spanish can be found in Comas (1969) with an English translation by Alfonso and Little (2005). Today, the AAPA (http://www.physanth.org/) has grown from its charter membership of 83 in 1930 to a

membership of nearly 2000 physical or, as often called, biological anthropologists. The early members were drawn from anatomical, medical, and anthropological professions, whereas contemporary membership is broadly represented by the biological, medical, and social sciences. It is the largest professional society in physical/biological anthropology in the world. Annual meetings often draw 1000 or more professional, associate, and student members and other attendees.

Major Impact

The professional goals of the Association are to promote and advance the development of research, education, and public outreach within the science of physical (biological) anthropology. Theoretical perspectives and the content of research in biological anthropology are derived from a number of sources. Of primary importance is *human evolution*, including past processes, as represented by human fossil remains and artifacts reflecting past human cultures. Human evolution is also studied as ongoing evolution, that is, the diversification of humans by microevolutionary and hereditary processes. Another theoretical focus is on the uncovering of patterns of *human variation* and its sources – evolutionary, developmental, and historical. A third theoretical focus derives from its anthropological roots: this is the search for *interactive biological and cultural/behavioral processes* that define us as human. Current subfields of biological anthropology include skeletal biology, bioarchaeology, forensic anthropology, human population genetics and molecular anthropology, human population biology, reproduction and child growth, paleoanthropology, and primatology. Each of these subfields is represented by members of the AAPA, and substantial cross-disciplinary research is conducted by these members and others from the biological, health, and anthropological sciences.

The AAPA officers include a President, either Past President or President-Elect, Vice President, and Secretary-Treasurer. The Executive Committee is constituted of these four officers, the two editors of the *AJPA* and the *Yearbook*, and four additional elected members. A new nonvoting member of the Executive Committee is a graduate student liaison. There are a number of specific subcommittees charged with issues of career development, education, history, awards, and the like. A Code of Ethics was prepared in 2003, and "Position Statements" cover a variety of topics that are germane to the profession. Some of these include positions on "Biological Aspects of Race," "Native American Graves Protection and Repatriation Act (NAGPRA)," "Teaching 'Scientific Creationism' in Public Schools," and "Disposition of Culturally Identifiable Human Remains."

There are two publications associated with the AAPA: *American Journal of Physical Anthropology* and the *Yearbook of Anthropology*. The journal, which began as a quarterly, is now published 12 times each year, with an additional issue devoted to the annual meeting program and abstracts. The *Yearbook* was founded in 1946 by Sherwood L. Washburn and Gabriel W. Lasker as an annual that originally published reprints of important articles that were not easily available to North American anthropologists, as well as reports of the Wenner-Gren Foundation summer workshops in the 1940s and early 1950s. During the 1970s, the Yearbook was reorganized to publish solicited and unsolicited reviews of important topics to the profession. The annual meeting, usually held in the spring, and which at its inauguration included 30 papers, now constitutes a program with more than 400 posters and 400 podium presentations. The AAPA annual meeting ordinarily meets for 3 days. However, there are a number of smaller sister societies that meet in conjunction with the AAPA which lengthens the meeting to 5 or 6 days. These societies are American Dermatoglyphics Association, American Association of Anthropological Genetics, Dental Anthropology Association, Human Biology Association, Paleoanthropology Society, and Paleopathology Association.

Numerous awards and sponsorships are provided by the AAPA for professional members and for student members. The Charles R. Darwin Lifetime Achievement Award (est. 1992) and the Gabriel W. Lasker Service Award (est. 2006) are

given annually. There is an Early Career Executive Committee Mentoring Opportunity that carries with it travel funding, and several Professional Development Grants for early-career, nontenured faculty or postdocs. The William S. Pollitzer Student Travel Awards to attend the annual meeting were given to more than 40 students in 2012. Finally, there are cash awards for Student Presentation Prizes given for outstanding poster or podium presentations. Five prizes are named after distinguished past members of the AAPA: Juan Comas, Earnest A. Hooton, Aleš Hrdlička, Mildred Trotter, and Sherwood L. Washburn. These awards and prizes recognize the achievements of senior and junior members of the AAPA, and they support the next generation of biological anthropologists as developing scientists.

The American Association of Physical Anthropologists is an active professional society that has been growing in membership since its beginning in 1930. With the exception of the WW II years, there have been annual meetings each year, and the journal will have its 100th anniversary in less than a decade (2018). Fiftieth anniversary (Boaz and Spencer 1981; Spencer 1982) and 75th anniversary (Little and Kennedy 2010) reviews of physical anthropology and the AAPA provide overviews at these time junctures.

American Institute for Conservation of Historic and Artistic Works (AIC)

Claudia Chemello[1,2], Susanne Rawson[3] and Molly Gleeson[4]

[1]Terra Mare Conservation LLC, Charleston, SC, USA

[2]The Kelsey Museum of Archaeology, University of Michigan, Ann Arbor, MI, USA

[3]School of Art History, Classics and Religious Studies, Victoria University Wellington, Wellington, New Zealand

[4]American Institute for Conservation of Historic and Artistic Works (AIC), Washington, DC, USA

Basic Information

The American Institute for Conservation of Historic and Artistic Works (AIC; http://www.conservation-us.org) is the national membership organization supporting conservation professionals in preserving cultural heritage by:

Establishing and upholding professional standards

Promoting research and publications

Providing educational opportunities

Fostering the exchange of knowledge among conservators, allied professionals, and the public

Incorporated as a nonprofit organization under article 501(c)(6) of the US tax code in 1972, its membership of over 3400 includes archaeological conservators who are active around the world.

AIC holds annual meetings in venues across the United States. General session themes range from the theoretical to the practical, while specialty group sessions focus on topics of particular interest to those practicing in fields ranging from architecture, books and paper, electronic media, paintings, photographic materials, textiles, and objects, including wooden artifacts and archaeological materials.

In addition to supporting the production and dissemination of a variety of online and print conservation publications, AIC publishes a peer-reviewed journal, the *Journal of the American Institute for Conservation*, which is available as a benefit of membership and on Conservation Online (http://cool.conservation-us.org/), on JSTOR (www.jstor.org), and, as of 2015, through Taylor & Francis (http://www.tandfonline.com/).

Major Impact

As the national body that represents archaeological conservators in the United States, the AIC provides professional standards and guidelines that directly pertain to the conservation and preservation of historical and archaeological resources. These include legal and ethical considerations for treating artifacts, professional conduct and respect toward various cultures and societies, educational and training guidelines, and guidelines for the examination and scientific investigation of artifacts which are applied to field excavations, in situ preservation, and conservation treatments used for archaeological materials. The AIC also encourages collaboration with allied professionals to ensure the best possible understanding and outcome in preserving our collective cultural heritage.

Within the AIC, the Archaeology Discussion Group (ADG) is a network of professional conservators who work with, or are interested in, the conservation of archaeological objects, structures, and sites. The ADG is a working group of AIC's Objects Specialty Group. Their members work in many different areas including for museums and other cultural institutions and organizations, in private practice, for archaeological or historical sites, as well as for teaching in academic programs. Many ADG members are also affiliated with national and international archaeological, scientific, and cultural heritage organizations. These include the American Association of Museums, the International Council of Museums and the Committee for Conservation, the International Institute for Conservation of Historic and Artistic Works, the Archaeological Institute of America, the Society for Historical Archaeology, the Society for American Archaeology, the American Schools for Oriental Research, and the Materials Research Society, which help to further promote conservation, and specifically archaeological conservation, worldwide.

One of the central goals of the ADG is to facilitate communication and collaboration between AIC and professional archaeological organizations in the United States. The AIC and individual members promote interdisciplinary relations with various professional archaeological organizations, including the Archaeological Institute of America, the Society of Historical Archaeology, the Society for American Archaeology, and the American Schools for Oriental Research through the presentation of papers and posters at annual meetings, through organizing and moderating specific sessions and workshops dedicated to conservation, and through AIC-sponsored exhibit booths at these conferences.

The AIC also provides scholarships and grants to aid in the professional development of members through workshops, publications, and outreach efforts and provides grant funding for specific conservation projects. In addition to these opportunities, the organization promotes safe practices through resources provided by the Health and Safety Committee. Disaster response and recovery can also be provided to archaeological sites and collections that have experienced damage through natural or man-made disasters.

American Pioneers and Traditions

David M. Carballo
Department of Archaeology, Boston University, Boston, MA, USA

Introduction

The Americanist tradition of archaeology is defined by cross-cultural comparative research that draws heavily on an innovative tradition of regional-scale fieldwork (Willey and Phillips 2001[1958]; Willey and Sabloff 1980). Many early pioneers worked in multiple culture areas of the Americas, seeking direct connections between the archaeological record and living or historical indigenous peoples, and fostering close ties with anthropology as a result. This brief overview covers seminal developments in stratigraphic excavation, regional survey, and other field methods within their historical and geographic context.

Definition

Pioneering archaeological efforts across the globe are often lauded for their early attention to stratigraphy and the association of geological or cultural strata with change in human societies over time. In the Americas, as in other parts of the globe, such attention was often the result of nonsystematic excavations into mounds of anthropomorphic origin. This was the case along Peru's arid coast, where immediately following the conquest Spaniards began excavating in adobe temples (known as *huacas*) in search of gold left by pre-Inca cultures such as the Moche and Chimú. A couple centuries later, a few early naturalists and proto-archaeologists began defining construction layers within such structures. A notable effort is part of a nine-volume record of the natural and cultural history of the region surrounding Trujillo, Peru, by its bishop, Baltasar Jaime Martínez Compañón, compiled in the mid to late eighteenth

century (Pillsbury and Trever 2008). Among remarkable watercolors and line illustrations of site maps, structures, and artifacts is a rendering of a labeled stratigraphic cut through Huaca Tantalluc, located near Cajamarca. It was made in 1765 by one of Martínez Compañón's predecessors, the magistrate Miguel Feyjoo, following a Spanish Bourbon dynasty mandate to explore and document its provinces. It may represent the first stratigraphic archaeological illustration in the Americas, before Thomas Jefferson's more widely known efforts in the US. Jefferson's excavation was undertaken in the 1770s or 1780s, with 1783–1784 being likely, and involved trenching through a burial mound near Monticello to understand its composition and correctly attribute its builders to the ancestors of the native peoples of the region (Milner 2004). Yet it took the systematic works of nineteenth-century scholars such as E. G. Squier, Edwin Davis, and Cyrus Thomas to completely dispel the "myth of the moundbuilders," which through prejudice and ignorance held that mounds of the eastern USA were built by peoples other than Native Americans.

Though pioneering, the attention to stratigraphy of a Feyjoo or Jefferson would not match our contemporary understanding of stratigraphic excavation. This began in the Americas in the early twentieth century, some two decades after its initial development in Europe, but then quickly became part of standard archaeological practice. The stratigraphy of the Emeryville shellmound, near San Francisco, was explored by the German archaeologist Max Uhle in 1902 and by the American Nels Nelson in 1906 (Nelson 1909; Uhle 1907). The Mexican archaeologist Manuel Gamio was a foundational figure in Mesoamerican archaeology and may be seen as the first person to link stratigraphic levels to cultural materials in developing a regional chronological sequence. Together with Franz Boas, his graduate advisor at Columbia University, Gamio developed a chronological sequence for Central Mexico in 1911 (Gamio et al. 1921). This work involved ceramic collections at six sites surrounding Mexico City and Gamio's excavation of nearly six meters of superimposed cultural layers at Azcapotzalco. Two years later, Nelson participated in stratigraphic excavations at the Palaeolithic cave site Cueva de El Castillo, Spain, and returned to New Mexico convinced of the importance of the methodologies he learned there, which he then applied to Southwestern archaeology through his work in the Galisteo Basin (Nelson 1914). The pace of stratigraphic work in these culture areas accelerated rapidly and spread elsewhere. Direct successors within these two regions include George Vaillant's excavations of nine Central Mexican sites, while a curator at the American Museum of Natural History, and Alfred Kidder's 15 years of investigations at Pecos Pueblo, sponsored by the Peabody Museums of Harvard University and of Phillips Academy (e.g., Kidder 1924; Vaillant 1937). Both projects were critical for establishing cultural sequences and served as benchmarks for future excavations in Mesoamerica and the Southwest.

Part of Franklin D. Roosevelt's New Deal put Americans back to work during the Great Depression by offering jobs as laborers on archaeological survey and excavation crews led by trained professionals (Fagette 2008; Lyon 1996). This boon to US archaeological research resulted in investigations in 36 states and included the widespread adoption of methods such as excavation by horizontal stripping, spraying sediments for better visibility of features and strata, plotting the post molds and pit features of perishable structures (Fig. 1), and the circulation of manuals on field and lab methods. New Deal archaeology also saw the professionalization of historical archaeology in the USA. Whereas earlier excavations had focused primarily on architectural restoration, J. C. Harrington's 1934–1941 investigations at Jamestown, Virginia, included excavations targeted especially at areas lacking architecture in order to document the ditches and fence lines that defined property boundaries, and the collection of all artifacts with special attention to context (e.g., Harrington 1955). Several pioneering women in archaeology also began their careers around this time (see Claassen 1994), including Elizabeth W. Crozer Campbell, who studied California desert cultures while at the Southwest Museum; Hannah Marie Wormington, who

American Pioneers and Traditions, Fig. 1 WPA trowelmen at work, Thompson Village Site, Tennessee. Image courtesy of the Frank H. McClung Museum, University of Tennessee (62HY5[B])

American Pioneers and Traditions, Fig. 2 Gordon Willey at Tula, Mexico. Gordon Willey Slide Archive, courtesy of William L. Fash

made significant contributions to Paleoindian research and was the first woman elected president of the Society for American Archaeology; and Betty Meggers, whose research in South America ranged widely during a long career at the Smithsonian Institution.

Gordon Willey (Fig. 2) launched the field of regional archaeology (aka landscape archaeology) with his 1946 survey of Peru's Virú Valley while working for the Smithsonian Institutions' Bureau of American Ethnology (Willey 1953), followed by over two decades of settlement research in Central America and Mesoamerica. His work transformed global archaeology by demonstrating that sites cannot be understood in isolation, nor should archaeologists focus exclusively on large or architecturally conspicuous sites; rather sites must be viewed holistically, as parts of ecological and cultural landscapes. Field methods in the Virú Valley included the production of site maps from

American Pioneers and Traditions, Fig. 3 Site sampling by squares and trenches at the Joint Site Pueblo, Arizona (Hanson and Schiffer 1975: Fig. 5). Image courtesy of the Field Museum

aerial photos, "ground-truthing" these maps in the field using a compass and measuring chains, recording details of site setting and architecture, and plotting all sites on a valley map made by the geographer F. W. McBryde. In North America, Willey's long-time collaborator Philip Phillips developed a similar approach during his 1940–1947 survey of the Lower Mississippi Valley, undertaken with James Griffin and James Ford, the latter of whom worked with Willey in Virú (Phillips et al. 1951). The greater use of test pits in the Mississippi Valley reflects the differences in surface cover and visibility between the arid coast of Peru and temperate woodlands of the

eastern USA, and full test pits or shovel test pits are much more common in surveys of densely vegetated regions of the Americas such as the Eastern Woodlands, Maya Lowlands, and Amazon Basin, compared to drier regions of western North America, and the highlands of Mesoamerica and the Andes.

The regionally oriented and stratigraphically deep research of Stuart Struever in the Lower Illinois Valley during the 1960s was highly influential for its use of multiscalar sampling strategies (within sites, ecozones, and regions) and of flotation as a means of recovering small ecofacts and artifacts (e.g., Struever 1968, 1971). Field sampling methods were further developed by projects such as the Chevelon Archaeological Research Project, directed by Fred Plog (1974), the New Survey of the Southwest Archaeological Expedition of the Field Museum (e.g., Hanson and Schiffer 1975), and the Prehistory and Human Ecology in the Valley of Oaxaca Project, directed by Kent Flannery (1976) and later codirected with Joyce Marcus. These projects emphasized the importance of some element of randomness in the placement of test units in order to minimize biases based on initial assumptions of the patterning of subsurface remains and to derive statistically significant samples upon which to build social interpretations. The choice of squares or trenches as sample units might be determined by the depth of deposits – as was done by Flannery and colleagues, who found trenches to be more efficient for deep sites in Oaxaca, thereby avoiding "telephone booth" style pits – or the strategies could be integrated at the same site, as was done by Hanson and Schiffer at the Joint Site Pueblo (Fig. 3).

Key Issues/Current Debates/Future Directions/Examples

The Americanist tradition of cross-cultural comparison drawing on regional archaeological datasets is exemplified by work such as Flannery's and by Robert McC. Adams's (1966) comparative study of urbanization in Mesopotamia and Mesoamerica. Building on this base of pioneering researchers, methods in American archaeology continue to develop, today increasingly incorporating new geospatial technologies and material sciences in the field. This is not only true of archaeology sponsored by universities and museums but also of Cultural-Resource Management (CRM), which is currently the public face of archaeology and the largest employer of archaeologists in the USA.

American School of Classical Studies at Athens (ASCSA)

Irene Bald Romano[1] and Jack L. Davis[2]
[1]University of Arizona, Tucson, AZ, USA
[2]University of Cincinnati, Cincinnati, OH, USA

Basic Information

The American School of Classical Studies at Athens (ASCSA) is America's first overseas research center and is still the largest in terms of assets, programs, and constituencies. It is a nonprofit organization based in the United States; its Trustees were incorporated in 1881 in Massachusetts for the purpose of founding the ASCSA in Greece. ASCSA's website is at http://www.ascsa.edu.gr.

Major Impact

Since its beginnings, ASCSA has provided American graduate students and scholars a base in Greece for pursuing studies in the history and civilization of the Greek world (Lord 1947; Meritt 1984). ASCSA remains today a teaching institution, providing through its academic programs, opportunities for graduate students, undergraduates, secondary school and college teachers, as well as other scholars to study at first hand the sites and monuments of Greece. ASCSA is also a major research center for postdoctoral scholars pursuing independent research in a broad range of fields in the humanities, archaeological science, and social sciences from antiquity to modern times.

ASCSA operates two internationally renowned libraries, the Blegen Library with approximately 110,000 volumes dedicated to Greece and related regions and cultures from prehistory to the end of antiquity and the Gennadius Library with over 120,000 volumes concentrating on the Greek world and Balkans after the end of antiquity to

the modern day, two archival repositories, and the Malcolm H. Wiener Laboratory for Archaeological Science. ASCSA sponsors two major excavations and related research centers at Corinth and in the Athenian Agora, administers other American excavations and research activities in Greece, and supports a major publications program, publishing up to ten titles per year and an award-winning, quarterly journal, *Hesperia* (ISSN: 0018-098X; E-ISSN: 1553-5622).

Many scholars of classical antiquity consider the Blegen Library to contain research collections in their field comparable to those at major research universities, while the Gennadius Library holds a diverse collection of books and rare bindings, manuscripts, works of art, and archival collections that pertain to Medieval and modern Greece. Important among the collections of the latter are first editions of Homer, rare Bibles, diaries of early travelers to Greece, unique maps of Greece and the Mediterranean, the diaries and letters of Heinrich Schliemann, and the papers of many of Greece's most important political and cultural figures, including Greece's two Nobel Prize-winning poets, George Seferis and Odysseas Elytis. The archives of the Blegen Library contain records of many important archaeological projects, as well as photographs and the personal papers of renowned archaeologists who have conducted work under its auspices (Vogeikoff-Brogan and Davis 2013; Vogeikoff-Brogan). Recent remodeling of both the east and west wings of the Gennadius Library has added an exhibition space and expanded facilities that will permit consolidation of all archival holdings of ASCSA. Founded in 1992, the Wiener Laboratory is one of the leading laboratories of its kind in Greece, especially in the fields of biological anthropology, zooarchaeology, geoarchaeology, and environmental studies (including the study of organic residues and botanical remains). An expanded state-of-the-art laboratory building was inaugurated in 2016.

ASCSA presents lectures, workshops, and conferences on topics related to Greece and neighboring regions in all periods. Lectures in the 200-seat auditorium, Cotsen Hall, are videotaped and made available on the ASCSA website. In addition, ASCSA's digital library, also available through the website, offers wide access to archaeological records from the excavations at Corinth and the Athenian Agora and research materials from the libraries and archives (http://www.ascsa.edu.gr/index.php/digital-library).

From its founding, ASCSA has sponsored excavations at major sites in Greece. Its excavations at Corinth began in 1896 and are one of the world's longest continuous projects, as well as serving as a training ground for generations of young archaeologists. Located on a hill above the strategic Gulf of Corinth, the ancient site is vast, encompassing over 6 km^2 within its walls; the more than 60 acres of the site that have been explored thus far include the acropolis of Acrocorinth, the city center, and its two ports on the Corinthian and Saronic Gulfs: Lechaion and Kenchreai. Excavations by ASCSA have documented Corinth's history and its territory from the Early Neolithic period (6500–5750 BCE) to the modern day (http://www.ascsa.edu.gr/index.php/excavationcorinth/). Some 45 volumes in ASCSA's Corinth series have been published, while other monographs and numerous articles in *Hesperia* also record the results of investigations.

The second long-term excavation of ASCSA is in the civic, political, and commercial center of ancient Athens, the Athenian Agora. Since 1931 ASCSA has excavated this large archaeological site in the heart of the city, documenting its 5,000-year history (http://www.ascsa.edu.gr/index.php/excavationagora/). Excavations have yielded finds ranging in date and character from pottery of the late Neolithic period (c. 3000 BCE) to the contents of nineteenth and twentieth century basements. The Agora of the fifth and fourth centuries BCE, however, has been the main focus of attention, and its exploration has revealed primary evidence for the functioning of the ancient Athenian governmental institutions that played a formative role in the foundations of western democracies. There are few ancient sites more

important in Greece, and none for which the excavation records are more critical for documenting the unparalleled achievements of Classical Athens. ASCSA has published some 40 volumes in a series on the Athenian Agora, as well as numerous other monographs, booklets and guidebooks for the general public, and scholarly articles in *Hesperia* and elsewhere.

Since its founding ASCSA has overseen numerous other excavations and surface surveys in many parts of Greece, though often with particular focus on the Peloponnese and Crete. Recent projects are at Gournia in eastern Crete, Thebes in Boeotia, the Sanctuary of Zeus at Nemea, the Sanctuary of Zeus on Mt. Lykaion, Arcadia, at Molyvoti in Thrace, and at the Palace of Nestor in Pylos (for a list of and links to other projects affiliated with ASCSA in recent years, see http://www.ascsa.edu.gr/index.php/fieldwork/Affiliated-North-American-Field-Projects).

Amheida, Archaeology of

Anna Lucille Boozer
Department of History, Baruch College and The Anthropology Program, The Graduate Center, City University of New York, New York, NY, USA

Introduction

Amheida is a substantial ancient settlement located in the northwest extent of Egypt's Dakhleh Oasis (Fig. 1). Amheida is a multiphase site that reached its greatest expanse under Roman rule (first C AD–fourth C AD). Its pharaonic name was Set-wah ("resting place") and it was known as Trimithis during the Roman Period. This site is the largest surviving ancient settlement within the oasis.

Amheida was one of the most important towns in the Dakhleh Oasis during the Roman and Byzantine centuries. Documentary sources indicate that it became a city by the fourth century and was regarded on the same level as other significant cities in the Oasis Magna, which consisted of Dakhleh and the Khargeh Oasis to the east (Wagner 1987). The diversity and extent of archaeological remains at Amheida attest to this significance. The substantial aboveground remains and surface pottery scattered across the urban center, and cemeteries extend from at least 2.5 kms north-south and 2 kms east-west. These remains represent dates ranging from Pharaonic to Late Antique periods, and the surrounding environs contain evidence of prehistoric lithic scatters, Old Kingdom ceramics, and several cemeteries. Despite a long occupational history, Late Antique ruins dominate the visible site surface today. The historical trajectory of Amheida complements that of the greater Dakhleh Oasis in that it reached its apex during the Roman Period.

Definition

Amheida, known as Trimithis during the Roman Period, was a significant urban site located in

Amheida, Archaeology of, Fig. 1 Map of Egypt. (Illustration: M. Mathews)

Egypt's Dakhleh Oasis. Despite this peripheral location, inhabitants sustained an existence that entangled Roman Mediterranean, Greek, Egyptian, and local traditions into their everyday lives.

Historical Background

History of Research and Excavation

Outsiders have known about Amheida since European explorers first ventured to Egypt's

Western Desert. Sir Archibald Edmonstone, a British explorer, became the first European to visit the oasis and Amheida in 1819. Renowned explorers, Bernardino Drovetti and Frédéric Cailliaud, visited the oasis shortly thereafter. Since its European discovery, both specialists and nonspecialists visited Amheida (Boozer 2013). The site came into prominence in 1979 when the Dakhleh Oasis Project (DOP) discovered classical wall paintings on the site during its survey of the entire Dakhleh Oasis (Leahy 1980).

Modern archaeological fieldwork began in 2000, directed by Roger Bagnall. It was first under sponsorship from Columbia University and then by New York University. Anna Lucille Boozer leads excavations in Area 1, initially as part of the University of Reading (2012, 2013) and currently as part of the City University of New York. Research has experienced delays due to external causes: in 2009 there was a delay in issuing security clearances; and in 2011 the team was evacuated after only a few days of excavation because of the Egyptian revolution. Since the revolution the approval of security clearances has not been as dependable as they were in prior years, and security restrictions on the entire Western Desert have been in place since 2015. These external causes have slowed the pace of excavation as well as the final analysis of excavated material for publication.

The chief areas of excavation include Area 1 in the northeastern part of the site, a fully excavated house (B2), a courtyard (C2) and its unexcavated house (B9), and the widest street (S1) at Amheida; Area 2 which is the current center of the archaeological site, a fully excavated house (B1), a *thermae* (bathhouse) under B1 and B4 (B3), a complex consisting of stables and post-abandonment rubbish disposal area located north of house B1 (B4), a school (B5), the Byzantine update of the earlier bathhouse (B6), a church (B7), a partially excavated house (B8), and a covered street (S2); Area 4, an elevated mound upon which the precinct of the Temple of Thoth was located; and Area 8, an urban area north of Area 2 and a house (B10). The project has also conserved a pyramid and a monumental mudbrick tomb in Area 3 in the southern part of the site (Fig. 2).

Key Issues/Current Debates

Town Planning

Survey continues to define the extent and form of Amheida's layout, although preliminary conjectures regarding the layout can be made at this time (Fig. 2). Amheida manifests a diversity of structure types, as can be expected for a major regional center. The houses seem to be single – or, in some cases, possibly two – story mudbrick structures with mainly barrel-vaulted roofs and some palm reed and mud flat roofs. Industrial areas can be found distributed among the domestic structures, but primarily along what we currently understand to be the edges of the city. A temple mound on the west side, around which the Roman settlement curves, and mortuary structures along the southern side are also clearly evident among the surface remains. Agricultural fields occupied the low-lying surrounding landscape. Governmental, administrative, or so-called public buildings, aside from bathhouses, have not been identified securely yet. Even so, it seems that the area just east of the temple mound may have been a focal point on the site as surface remains indicate a number of large, elaborate structures that may have served civic functions. The excavated houses and public baths closest to this area appear to be high status. The first church discovered at Amheida also is located here.

There are two major streets currently identifiable at Amheida. First, a broad east-west oriented road (S1) provided access into the city from the east. It leads from the industrial and domestic area on the northeastern extent of the site toward an area north of the temple mound, but it turns sharply off axis and then stops abruptly before reaching the temple mound itself. It is the widest identified road at Amheida at nearly seven meters wide. It appears that the road and the structures along its easternmost extent may have been built during a single phase of construction (Boozer 2014).

The second major street is a north-south oriented road (S2) that extends from the mortuary area in the southeastern portion of the city to the north. This road appears to have had structures built into it over time, which made it less effective

Amheida, Archaeology of, Fig. 2 Plan of Amheida. (Courtesy of the Amheida Project)

as a major conduit across the city. In addition to these major roads, there are some less-fully traced out streets and alleys. One runs roughly parallel to the major north-south road and is located between this road and the temple mound. Some additional east-west aligned streets also occur. Curiously, the project has not yet identified any streets connecting the eastern settlement area with the temple mound, nor has any trace of the temple dromos been found. There are several areas that indicate localized planning. For example, the northeastern part of the site appears to have been laid out in a single phase, and the structures in this area share similar plans. An area located in what appears to be the center of the Roman site also contains houses that, from the surface, appear to share similar layouts. Likewise, in an area just south of the temple, a series of roads delineate the eastern boundary of a housing block where at least one significant, decorated house is identifiable on the basis of surface architecture (Bagnall et al. 2016; Boozer 2014).

Domestic Structures

Domestic structures have been a key focus of this project since its inception, and this project has made a major contribution to our understanding of Romano-Egyptian domestic life. There are

Amheida, Archaeology of, Fig. 3 Plan of House B1 and School B5 in Area 2. (Courtesy of the Amheida Project)

Amheida, Archaeology of, Fig. 4 *Polis* from House B1, Room 1 in Area 2. (Courtesy of the Amheida Project)

three main houses: B1 and B2, which have been excavated fully, and B10, which has been excavated partially. Two other houses have undergone preliminary investigation only: B8, south of B1, and B9, east of B2.

A fourth-century house (B1) is a lavish dwelling that contained Greek mythological wall paintings in a central, domed room and wallpaper motif wall paintings in a number of side rooms (Figs. 3 and 4). The figural scenes are the only ones of their kind so far discovered in Roman Egypt. They inform us that occupants of the oasis were engaged with Roman Mediterranean cultural norms (Boozer 2010). A 2015 survey of wall paintings at Amheida corroborates this conjecture and further emphasizes that this site will make a major contribution to our understanding of wall paintings in the Roman World (Bagnall et al. 2015b).

Measuring approximately 15 × 15 m, this house was essentially square in plan view and had a clustered plan of access between rooms. It was constructed out of mudbrick with selective use of baked brick, which appears to have been reused from the dismantling of an earlier bathhouse, which this house partially covers. Most of the rooms in this house were covered in barrel vaults, although one room contained a dome, potentially with an oculus, and there were flat roofs constructed out of palm reeds and beams with a mud plastering over at least two rooms. The stratified objects recovered from this structure suggest that it was built around 330 AD, was renovated in two subsequent phases, and then definitively abandoned in approximately 365 AD (Bagnall et al. 2016).

Damp conditions did not preserve soft organic materials as well as at other sites within the oasis,

particularly Kellis (Ismant el-Kharab), or at other areas at Amheida (namely, area 3). Among the material that survives is a substantive corpus of *ostraka* (potsherds with writing), which provide information about the owners of this structure, dependency relationships within the region, small-scale economic data, and also political information because one of the owners was a city councilor (Serenos) (Bagnall and Ruffini 2004; Bagnall and Ruffini 2012). Among the few objects recovered during excavation were bronze rings, one gold ring, bone hairpins, glass bracelets and beads, and a few bronze coins. Ceramics are of a generally high quality with respect to the local assemblage, and there are other artifacts that point toward higher status occupants. Preliminary analyses of faunal remains suggest that the occupants consumed foods common within the broader Roman Empire, such as chicken and pork. As an assemblage, this evidence suggests that the inhabitants sustained an existence looking more toward the Mediterranean than one might have expected, given the peripheral location of the site. In the last occupational phase of the house, some floors were replastered and others replaced. Bands of whitewash were added around the niches, doors, and walls of some rooms. Storage bins were built inside one room and a small cooking hearth was added in another room. Together, this renovation evidence suggests that the house was redesigned to be more functional than decorative. The reasons for the redesign are not clear at this time (Bagnall et al. 2016; Boozer 2007, 2010, 2012).

The vicinity around House B1 has also been explored. South of House B1 lies another, partially excavated house (B8) with an identical overall footprint and a similar layout within. The stratigraphy and object assemblage recovered from the only excavated room suggest that it may have had a somewhat different occupational history from that of B1: there was a higher density of objects, and most of them appear to be goods used by women. The street (S2) in front of an informal entrance to B1 was covered with a flat roof made out of palm beams, a common feature of medieval settlements in the Dakhleh Oasis. There was an open space in front of the entrance to the house where a dining area (*stibadium*) was constructed (Fig. 3). Based upon the stratigraphy of the street, this dining area appears to have been short-lived. It was demolished and paved over during the occupational history of the house. The opening in front of the house entrance created a natural updraft which creates a cooling effect; this feature is also found in local medieval settlements. Although S2 once connected Houses B1 and B8, it was later blocked off, suggesting that there may have been a change in the relationship between the two households (Bagnall et al. 2016).

A mid-late third- to early fourth-century AD house (B2) was also excavated in its entirety (Fig. 5). This house is located in the northeastern part of the site in an industrial and domestic quarter. The house measures approximately 11 × 11 m. Like the larger house (B1), this structure is constructed out of mudbrick, demonstrates a clustered plan of access over its square plan, and employed barrel-vaulted roofs over most rooms and a flat palm-and-mud roof over one room. No evidence of roofing was recovered from the central room, which also had a bread oven, which suggests that it may have been uncovered. Cooking facilities are present within two different rooms in the house, suggesting potential changes in food preparation practices or different facilities used for different types of cookery. The other room with cooking equipment was located in the corner of the house and was covered with a flat roof (Boozer 2015a, b).

The material culture from House B2 was preserved in great densities and included a small percentage of organic remains. The animal bones include chicken, goat, donkey, cattle, and even wild gazelle, which suggest traditional Egyptian influences upon an otherwise standard diet for the time. Archaeobotanical evidence indicates that occupants consumed emmer wheat, a traditional Egyptian grain nearly unattested in documentary sources of this period. Additional objects and texts suggest a range of activities including linen weaving, trade, and low-level water management. This evidence indicates that the inhabitants of this house, or at least people living in its vicinity, may have participated in the small-scale management of production and transportation activities. Future

Amheida, Archaeology of, Fig. 5 Plan of House B2 in Area 1. (Courtesy of the Amheida Project)

research in this neighborhood may provide useful avenues of research into mid-level economic relationships. It is notable that the density of written evidence was substantially lower in this house than in House B1 and that one inscribed object, a clay tablet, conforms to a unique local oasite practice (Fig. 6). During the Roman Period, inscribed clay tablets have only been found at Amheida and Kellis. Two others come from Balat and date to the Old Kingdom. This object therefore appears to represent some sort of local practice of writing on unbaked clay (Ruffini 2015). As a whole, the domestic assemblage shows a combination of oasite, pan-Egyptian, Greek, and Roman influences. This range may indicate that the inhabitants had mixed ethnicities, that social status linked with ethnic material goods, or that the inhabitants did not have a vested interest in ethnic identity (Boozer 2007, 2011, 2015a, b).

The vicinity around this house has also been explored (Boozer 2016). A courtyard exterior to the house (C2), but belonging to the house east of B2 (B9), contained a bread oven with a platform and appeared also to have served as a stable for animals such as donkeys. Small dumps of material found above floor level suggest that it was reused for rubbish depositions after its abandonment. Numerous objects relating to domestic life were found in this courtyard, including figurines, a palm reed broom, a broach, cloth fragments, a bracelet, and so on (Fig. 7). While these objects cannot be connected directly to the occupational history of the courtyard in most cases, they likely connect to habitation in the vicinity.

The street adjacent to the house (S1) was also excavated, revealing multiple street levels as well as foundation trenches in common between the houses (B2 and B9) and the street. This suggests that this part of Area 1 was laid out in a single phase of construction (Boozer 2015a). House B9 has not been excavated yet although from the surface its layout appears to be similar to that of

House B2. The Dakhleh Oasis Project cleaned and mapped the surface of a structure across the street from House B2 in 1979, revealing a house that was subsequently provided with kilns for small-scale ceramics production (Hope 1980). These two houses will be the focus of future excavation seasons.

Amheida, Archaeology of, Fig. 6 Clay tablet inscribed in Greek (Inv. 11,048) from House B2, Room 7 in Area 1. (Courtesy of the Amheida Project)

During the 2015 field season, new excavations commenced on House B10, located in Area 8.1, which is north of Area 2 and west of Area 1. On the basis of the finds recovered, chiefly ceramics and *ostraka*, the excavators suggest that this house dates to the fourth-century CE. House B10, measuring approximately 30 × 26 m, has an irregular plan consisting of a northern and southern part. The main entrance to the house appears to have been from the north: an alleyway leads to an entrance room followed by a grand hallway, which was plastered in lime and decorated with geometric motifs on its lower elevations. This grand hallway appears to have been covered in a flat roof and to have had molded decorations rendered in gypsum. Additional rooms in the northern portion of this house were explored, and evidence of white and black painted plaster were identified in one. The southern portion of the house, measuring approximately 9 × 7 m, is architecturally more elaborate than the northern portion of the house. One room, with four columns supporting a flat roof, gave access to additional rooms. One of these rooms was covered with a vault. Excavations in this same room revealed numerous pots (complete and broken), 81 well tag *ostraka* written in Greek, and a bronze ring. Well tag *ostraka* are tags that were once

Amheida, Archaeology of, Fig. 7 Unfired clay figurine wearing a bracelet from Courtyard C2 in Area 1. (Drawing: S. Lambert-Gates, Courtesy of the Amheida Project)

attached to jars, giving a personal name, a date, and a place. The place name corresponds to a typical formula: "*pmoun* (well) + place name." The abundance of such tags found across Amheida indicate the importance of wells within this desiccated landscape. From the documentary evidence, we know that it was possible to own partial shares in wells as well as the land around the well but not the water itself. These complicated economic arrangements for water persist in the oases to this day (Boozer 2015).

School and Thermae

In the course of excavating the environs of House B2 in Area 1, the project uncovered evidence of bathhouses as well as a school.

B5, a building consisting of three rooms located along the north end of House B1, appears to have been used to educate children and youths (Figs. 3 and 8). Red dipinti on the walls indicate that these pupils were educated in Classical Greek traditions and particularly rhetorical verse composition (Cribiore et al. 2008; Davoli and Cribiore 2010). This school is the first of its kind to be located anywhere within the Roman Empire. Subsequent to its use for education, one room was reused as a storage magazine connected to House B1 and others as a workshop and stable (Bagnall et al. 2016).

Multiple phases of *thermae* (public bathhouses) have been discovered at Amheida (Fig. 9). Bathhouse B3, which is located underneath House B1 and the functional area north of it (B4), appears to date to the third century AD or perhaps even earlier. It was constructed out of mud and baked brick and measures approximately 41 × 34 m. Only a fraction of this structure has been excavated thus far, due to the overlying domestic structures and additional standing walls. On the basis of the current evidence, Paola Davoli has suggested that there were two major building phases; the initial phase sometime during the first centuries AD followed after a period of abandonment by a full remodeling (Bagnall et al. 2016; Davoli 2017).

B6 appears to be a public bath constructed after what Davoli estimates as a 40- to 60-year period of abandonment during which the earlier bathhouse (B3) was reused for rubbish depositions. The later bath structure is rectangular in plan view, measuring approximately 18.5 × 31.5 m, and is distinguished by a central, columned room. Some 23 rooms and pools have been identified, but their precise functions are not understood at this time and may never be understood due to their poor level of preservation. Water for the bath probably derived from a well southeast of the bath. A *sakia* (paddle-driven water-lifting wheels) would have brought the well water into the underground water

Amheida, Archaeology of, Fig. 8 A wall showing a poetic *dipinto* in a schoolroom, Room 15 in Area 2. (Courtesy of the Amheida Project)

Amheida, Archaeology of, Fig. 9 Plan of the *thermae* in Area 2. (Courtesy of the Amheida Project)

distribution system, which then conveyed it to the baths. Wastewater appears to have been deposited north of the baths using a sewer system (Bagnall et al. 2016; Davoli 2016).

Davoli has identified two renovation phases within this structure, during which some rooms were demolished and rebuilt and new ones added. She has also described two main parts to the bath: to the west was the cold and dry bath, as is suggested by the presence of mud-plastered floors and walls, and to the east was the hot and wet bath, as is indicated by the use of waterproof baked brick and hydraulic mortar. Presumably the cold area (*frigidarium*) was used for socializing, as is indicated by the benches which lined the west and south-west walls of the pillared central room. This area also possessed a communal toilet (*latrina*). The hot area (*calderia*) was used for typical bathing activities as indicated by the presence of two pools, one square and one round. A dry heat room designed for sweating (*laconium*) was round and constructed out of mudbrick. It had a suspended floor composed of thin tiles and white plaster. The floor was later relaid with wooden planks nailed into crossbeams. So far, this *laconium* is unique in Egypt. The hot area was accessed by crossing what was presumably a warm area (*tepidarium*) from the cold area. Although the excavation and analysis of the structure are not yet complete, Davoli believes that it represents a typical Late Antique bathhouse from this region. The bath was abandoned abruptly; a mosaic floor was left incomplete along with the *tesserae* that were being cut for it. After its abandonment, at the end of the fourth century, it appears to have been reused for various functional activities and for depositing rubbish. Even later, perhaps during the Mamluk Period, some of the building materials appear to have been robbed (Ast and Bagnall 2017; Bagnall et al. 2016; Davoli 2017).

Temple

Amheida's temple was dedicated to the Egyptian god Thoth, god of writing and wisdom. The temple itself, although looted in antiquity and again in more recent times, has provided substantive information on the occupational history and religious life within the Dakhleh Oasis. Excavations of the

numerous Ottoman looter pits that dot the temple mound have indicated that the site was occupied since at least the Old Kingdom, and the material recovered from these excavations suggests that there may have been a settlement located on what became the temple mound in later years. Paola Davoli has estimated two main periods of activity during the dynastic era: the end of the Old Kingdom to early First Intermediate Period and the 13th Dynasty to the Second Intermediate Period. Textual and decorative evidence, such as an *ostrakon* with a *Kemyt* text (apprentice writing), then suggests a return to activity in the 19th Dynasty when there appears to have been a school attached to the New Kingdom temple (Kaper 2010). The discovery of a large stela of King Seti II from the 19th Dynasty confirms the presence of a school and depicts the king making offerings to Thoth and Horus, among other gods (Bagnall et al. 2016) (Fig. 10).

The epigraphic material from the temple, which has been studied primarily by Olaf Kaper, has provided a particularly important collection of cartouches with pharaonic and imperial names that indicate governmental investment in this region. The recovered cartouches provide us with some of the construction history of the temple and associated chapels, although interpretations may change as they are based on a highly fragmentary data set. Under Takelot III (r. 774–759 BC), a stela was erected recording a land donation to the temple. Minor building took place under the Theban 23rd Dynasty (King Pedubast circa. 800 BC) and the early 26th Dynasty (Nekau II (610–595 BC) and Psamtik II (595–589 BC)). Major construction seems to have started under Amasis/Ahmose II (569–526 BC) and the Persian ruler Darius I (522–486 BC), both of whom contributed a new chapel with vaulted ceiling. The Roman Emperor Titus (79–81 AD) built a new Roman Period temple on the site, and Domitian (AD 81–96) both demolished older structures and contributed a new larger sanctuary, which was extended under later emperors, as yet anonymous (Kaper 2009; Kaper and Davoli 2006).

Amheida, Archaeology of, Fig. 10 Stela showing Seti II making offerings to Thoth and Horus (Inv. 16,309) from the Area 4 temple mound. (Courtesy of the Amheida Project)

The epigraphic material also provides us with some intriguing clues about local oasite traditions. In the Third Intermediate Period, Dakhleh was ruled by an Egyptianized Libyan tribe, called the Shamain (Kaper 2009; Kaper and Demarée 2006). This epigraphic material suggests that these late dynasties incorporated the oasis much more thoroughly into their regional ruling than had been attested previously. Moreover, the Persian Period finds have provided some of the most substantial indications of a Persian presence in this distant oasis.

The material culture recovered from the temple mound includes fragmentary glimpses into local cultic practices and the occupational history of Amheida. For example, ceramic coffins containing un-mummified animals were recovered from the temple mound. Such deposits were common from the Late Period through the Roman Period and served as votive offerings. The remains included a range of birds (raptors, ibis) as well as other animal fragments. The ibis was long associated with Thoth, while the raptors should be associated with other gods venerated in the oasis such as Horus or Re-Horakhte.

Offerings to Osiris were also found in the form of 45 bronze statuettes, fragments, and pendants of the god. In addition to these finds, ceramics dating back to the Old Kingdom have been recovered, including large quantities of bread molds. *Ostraka* in hieratic, demotic, and Greek further attest to the long and complex occupational history in this area of the site (Bagnall et al. 2016).

Christianity

Documentary evidence found primarily where the temple of Thoth was once located (Area 4) suggested the existence of a Christian community at Amheida before it was attested archaeologically. This written evidence consisted of titles of clergy members and personal names written on *ostraka* (Bagnall and Cribiore 2012). Additional graffiti, also found on the temple mound (Bagnall et al. 2016), signify a Christian presence.

In 2012 Nicola Aravecchia began excavation on a structure in Area 2 that he subsequently identified as a fourth-century church (B7). This building consists of a central nave with side aisles that were defined by two rows of mudbrick columns. These colonnades were oriented east-west and seem to have been joined together with a return aisle. Together these features created an interior ambulatory, which is a feature commonly found in other fourth-century Upper Egyptian churches. The foundations of what may have been a pulpit have also been identified at the east end of the north colonnade. A *mastaba* (bench) was found against the inner face of the south wall of this room. The east wall has a stepped rectangular platform, which may have stood at the location of the building's apse, which is now lost. Additional decorative features were found amid collapse depositions, namely, a fragment of wall plaster with the inscription *ho theos* (Greek: "God") and painted plaster fragments from the flat roof that once covered this room. These fragments represented a geometric motif may have been intended to imitate a coffered ceiling. While additional research remains to be done in order to understand the life history of this structure, the 3-m deep foundations make it clear that a considerable labor effort went into constructing this monumental building (Bagnall et al. 2016).

To date, eight human burials have been found inside of the church. Each of the bodies was oriented with their heads to the west, as was standard for Christian burials in the Dakhleh Oasis, and lacked grave goods. Preliminary results from osteological analysis by Tosha Dupras and Lana Williams indicate that these bodies were male and female and belonged to a wide range of ages. Three of the eight bodies are derived from a funerary crypt which was located underneath what may once have been the sacristy (*pastophorion*) but is now destroyed. There may be more to this crypt and to the church more broadly as excavation in this area has not been completed yet (Bagnall et al. 2016).

International Perspectives

Amheida offers a well-preserved archaeological site that was incorporated to greater and lesser degrees into larger imperial structures. The high state of preservation and diversity of structures at this site ensures that the entanglements between episodic imperial formations – Egyptian, Persian, Greek, Roman, and Arab – and local life can be investigated from a variety of vantages.

Future Directions

Topographic survey will continue to expand and fill in detail to the urban and cemetery layout of Amheida, and excavations will continue in the areas previously investigated in order to deepen our understandings of the environs surrounding excavated structures. For example, excavations in House B10 in the north of the site have only just begun. These excavations will continue to refine our understanding of the distinctions between public and private architecture in this site, since this and other domestic structures in Dakhleh are much larger and more opulent than previously suspected. Excavations will continue in the vicinity of the third-fourth-century house (B2) in order to understand neighborhood affiliations, small-scale production, and ethnic affinities in Roman Egypt. Likewise, additional research will take

place on the temple mound in order to recover additional information about the construction history of this temple, the occupational history of Amheida, and the history of the oasis in general. Geological and geomorphological surveys will continue in the future to understand the landscape of the city and of its surroundings. The project also intends to build upon the mortuary and physical anthropological component begun with the church excavations in the near future.

Amphitheater

Hazel Dodge
Department of Classics, Trinity College Dublin 2, Dublin, Ireland

Introduction

The amphitheater is one of several classes of building that were developed to accommodate a range of entertainments and spectacles in the Roman world. It was an exclusively Roman architectural development and was traditionally associated with gladiatorial display, although it came to accommodate animal displays and executions as well. As a building type, it was relatively late in reaching its canonical form and acquiring the associated facilities. Debates about the origins of both the structures and the types of display have monopolized scholarly attention, although recent research has clarified many points (Futrell 1997; Welch 2007). Partly as a result of senatorial opposition as well as cultural conservatism, permanent amphitheaters were not constructed in the city of Rome until the very late first century BCE, despite the fact that they were being provided earlier for other cities in Italy (e.g., at Pompeii). In the provinces, most amphitheaters were constructed in the first to early third centuries CE corresponding to the chronology of epigraphic evidence for arena displays, though it should be noted that not every city had one, nor were they always constructed on a monumental scale (Dodge 2014a, b). In the Eastern Mediterranean, a more complex situation prevailed which involved the limited provision of purpose-built amphitheaters and the much wider modification of preexisting entertainment venues for arena displays (Dodge 2009).

Definition

The permanent amphitheater is recognizable by its elliptical plan, with an oval arena completely surrounded by seating (Golvin 1988; Welch 2007; Dodge 2014a, b). This is the literal meaning of the Greek word *amphitheatron*, which from the time of Augustus gradually came to be used for this structure (Vitruvius, *de Arch* 1.7.1; *Res Gestae* 24; see also Dio 43.22). The earliest, datable permanent amphitheater is at Pompeii (Italy), and in the dedicatory inscription (*CIL* 10.852, 70–65 BCE), it is termed as *spectacula*, a word usually used for the entertainments themselves, and one clearly employed here because such buildings had yet to acquire a specific terminology.

Gladiatorial displays (*munera*) had their origins in aristocratic funerary rites at Rome and as such played an important role in elite display and competition in the Republic. They were staged in the Forum Romanum, the traditional location for aristocratic funerals, and the temporary spectator facilities required for the displays became increasingly elaborate. These facilities may have provided a model for the ovoid plan of early

permanent amphitheaters elsewhere in Italy (Golvin 1988: 56–58; Welch 2007: 30–71; Dodge 2014a). Investigations during the mid-twentieth century under the paving of the Forum Romanum located a central corridor, with four lateral arms bisecting it at regular distances 15 m apart, which excavators dated to the mid-first century BCE. Twelve shaft openings grafted access up into the open piazza. Traces of installations in these galleries are reminiscent of the system of cages and pulleys for winching performers and animals up into the arena that would later be installed beneath the arena floor in some developed amphitheaters of the imperial period (Coleman 2000: 227–228; Dodge 2014a, b). The amphitheater at Pompeii was dedicated by C. Quinctius Valgus and Marcus Porcius, *duoviri* of the new colony established at Pompeii in 80 BCE; they paid for the structure with their own money and in accordance with their magistracies (Golvin 1988: 33–37; Welch 2007: 74–77). The building was located just within the eastern city walls and measures 135 by 105 m. In common with other early amphitheaters, it was not provided with the extensive vaulted substructures, and the main support for the seating was formed by upcast from digging out the sunken arena. The exterior retaining wall at the upper level was built of *opus caementicium* faced with *opus incertum*, strengthened by buttresses, and with staircases that provided spectator access to the top of the *cavea*. At the north and south ends were broad, sloping corridors leading down into the arena. It was not until 29 BCE that Rome received its first permanent amphitheater, built by T. Statilius Taurus. It stood in the southern Campus Martius and was financed by the *manubiae* (a general's share of the booty) he received from his successful campaigns in Africa (Dio 51.23.1; Suetonius, *Augustus* 30.8; Golvin 1988: 52–53; Welch 2007). Little is known about it except that it was small and built of stone and wood; Dio referred to it as a "hunting theater" (*theatron kunegetikon*) and probably it was never used as a fully public venue. It was destroyed in the fire of 64 CE.

Key Issues/Current Debates/Future Directions/Examples

Key Example: The Colosseum

The most famous, largest, and most influential of all amphitheaters in the Roman world was the Flavian Amphitheater in Rome, better known today as the Colosseum (Gabucci 2001; Lancaster 2005; Welch 2007; Dodge 2019) (Fig. 1). It was begun by Vespasian on the site of the drained lake of Nero's Domus Aurea and dedicated in 80 CE by Titus after his father's death (Alföldy 1995). This was a grand and monumental building of four stories, 52-m high, standing on elliptical concrete foundations 12 m deep. It was an astonishing feat of planning and engineering on an unprecedented scale. With outer dimensions of 188 by 156 m and an arena measuring 80 by 54 m, an estimated 100,000 m^3 of travertine was used for the façade with 300 t of iron needed to clamp the blocks together. A combination of construction materials was used: concrete, travertine, and tuff, which allowed architects to address the specific structural challenges inherent in its design. The vaulted substructures beneath the *cavea* comprised a series of passages, corridors, and staircases. The three outer arcades formed two outer, annular corridors 7-m high covered by concrete barrel vaults. One further ring corridor closer to the arena was constructed of brick-faced concrete with a veneer of marble; this particularly grand passageway was used by those accessing the ringside seats set aside for the elite. These annular passages were intersected by the radial passages that accommodated staircases, superbly organized for ease and control of access. Although the access system had been used in both the theaters of Marcellus and of Pompey in Rome, here it was perfected so that the building perfectly incorporated the functional demands of a segregated society into its fabric (Edmondson 2002).

The design of the façade, broken up by arches, was framed by traditional orders (Tuscan, Ionic, and Corinthian) and helped to relieve the visual heaviness of the building. A similar treatment had already been employed for the exterior of the Theater of Marcellus (ded. 13 BCE). The topmost

Amphitheater, Fig. 1 Colosseum, view of the arena

level of the Colosseum facade, possibly not completed until the reign of Domitian, was a plain wall with windows alternating with Corinthian pilasters. It is at this level that the corbels for the awnings (*vela* or *velaria*) are preserved. Beneath the now lost wooden floor of the arena is an elaborate system of subterranean passages and chambers where animals and gladiators were held in readiness and winched up to the arena level or let up along ramps (Connolly 2003; Lancaster 2005). These had a very simple arrangement in wood at the time of the inauguration, such that scholars have suggested that the arena could have been flooded for full-scale aquatic displays, as implied by the literary sources (Dio 66.25.2-4; Coleman 2000; Gabucci 2001; Connolly 2003). There is still much debate about the logistics of such an enterprise, made more difficult by the fact that the arena substructures (*hypogeum*) have been much refurbished and rebuilt over time (Dodge 2019). However, such substructures and their access points can be better appreciated in the amphitheaters at Capua and Pozzuoli in Campania. Here the arena floors of concrete are still in place, and the trap-doors for hauling up animal cages can still be clearly seen (Golvin 1988; Dodge 2014a).

Welch has demonstrated that the provision of amphitheaters in Italy and the western provinces during the late republican and early imperial periods was linked to army training, and to veteran settlement and entertainment, as at Pompeii and Capua (Welch 2007: 88–91). These first permanent amphitheaters came to represent an important display of Rome's power and culture in Italy, and late first century BCE colonies also provided the context for the earliest amphitheaters in the provinces, as at Carmona (Spain), Corinth (Greece), and Antioch-on-the-Orontes (Turkey) (Golvin 1988: 41–42; Welch 2007: 255–259; Dodge 2009, 2014a). In the early imperial period, this colonial association continued within Italy, for example, at Aosta and Verona. Both colonies and provincial capitals provided important contexts for amphitheatrical building projects in the western provinces, as at Lyon (France), Mérida (Spain), and Carthage (Tunisia) (Golvin 1988: 82–83, 109–110, 122–123; Bomgardner 2000: 128–141). However, this is a pattern found with less frequency in the provinces of the Roman East (Dodge 2014a, b).

Amphitheaters in the Provinces

Amphitheaters survive in large numbers in Italy, North Africa, the Danube region, and the Western provinces, although with much variation in size and design, for example, at Capua (170 m by 139 m), second in size only to the Colosseum; Nîmes and Lyon (France); Carthage, El Djem (Tunisia); and Lepcis Magna (Libya). Extramural amphitheaters were also built and survive at some *civitas* capitals in Britain, as at Silchester and Cirencester (Wilmott 2008). Legionary bases around the empire were routinely provided with an extramural amphitheater, for example, at Vetera (Germany), Caerleon and Chester (Britain), Carnuntum (Austria), and Lambaesis (Algeria) (Golvin 1988: 80, 88; Futrell 1997: 147–152). All are relatively small, both in overall size and scale of construction.

In the British and Gallic provinces a hybrid structure, built to function as both theater and amphitheater, was often constructed, for example, Les Arènes in Paris (France). It is unclear if these "theater-amphitheaters" (also, confusingly, referred to as "semi-amphitheaters" by some modern commentators) were more amphitheater than theater, and it is uncertain what kind of performances took place in them (Golvin 1988; Dodge 2009). They were generally not elaborately constructed, utilizing earth banks retained by masonry walls as supports for the seating (*cavea*). Similar theater-amphitheaters were also associated with rural shrines in Gaul, as at Sanxay, and these perhaps should be interpreted as a continuation of the classical connection between temple and festival games as seen in the Greek sanctuaries at Delphi and Epidauros, and continued in Italy, for example, at Pietrabbondante. The only example of this type of hybrid theater-amphitheater outside the Northwestern Provinces is at Lixus in Morocco (Golvin 1988). There may also have been an economic element in this design, maximizing the facilities available in a single building (Dodge 2014a).

By comparison with the West, there are far fewer purpose-built amphitheaters known in the eastern Roman provinces (Dodge 2014a, b). This has been traditionally explained by the idea that the Greek East was more "civilized" than Italy and the Western Provinces and therefore would not have indulged in the kind of blood sports these structures accommodated. However, at least 22 purpose-built amphitheaters have already been identified in the East (Dodge 2009). The earliest example was constructed at Antioch-on-the-Orontes in the later first century BCE (Malalas 216.21-217.4; Libanius *Orations*, 2.219). Malalas referred to it as "a place of single combat" (*monomachikon*). The simple form of this building, partly rock-cut with no arena substructures, was probably similar to other contemporary amphitheaters known in Italy and the West, for example, at Paestum (Italy) and at Carmona. None of the amphitheaters in the Roman East have the monumentality and arena substructures seen in the West, as Nimes, Mérida, or El Djem, except perhaps Pergamum and Cyzicus (Turkey) (Golvin 1988; Dodge 2009) (Fig. 2).

Problems of Definition

There are many venues that do not fit simple modern characterizations, both in terms of ancient terminology and the range of events staged within them. This is particularly true of the eastern empire that had an already existing building stock of theaters and stadia. What has become clear in recent years is the extent to which venues were modified and remodeled to maximize the flexibility for staging a range of entertainments. This was achieved in a number of different ways. In theaters, the most common method was the construction of a wall around the orchestra, often with the removal of the lower rows of seats and the reduction of the stage-building to create an arena-like space, as at Corinth (Dodge 2009); the removal of the seats created a high podium wall providing both protection and better viewing for the spectators. These modifications are mainly second century CE in date, or later, but some occurred as early as the first century CE, as at the Theatre of Dionysus in Athens. Stadia were adapted in a similar way at the curved end of the structure to create a mini-arena, for example, at Perge (Welch 1998, 1999; Dodge 2009).

Very few entertainment buildings have been fully excavated and properly published, making their dating and structural history

Amphitheater, Fig. 2 Pergamum. Amphitheater

problematic. Despite the massive scale of construction and public investment, some have been completely lost. Thus, new discoveries in recent decades have been particularly important, advancing knowledge in the provision of these buildings and the engagement of the local populations in typically "Roman" cultural pursuits. For example, an amphitheater was identified and excavated in the late 1980s and 1990s in London, the provincial capital of Britannia (Bateman 2008). The identification in 2006 of an amphitheater at Sofia (Bulgaria) has made another addition to the lengthening list of amphitheaters in the Eastern part of the Empire, further emphasizing that Roman spectacles were enjoyed as much in the Greek East as in the Latin West (Welch 1998, 1999; Dodge 2009; Velichkov 2009).

The most northerly amphitheater occurs in a military context in Scotland associated with the Antonine fort of Inveresk (Wilmott 2008); the most easterly examples have been identified at Palmyra in the Syrian desert and Dura-Europos on the Euphrates (Rostovtzeff et al. 1936: 72–77; Golvin 1988: 139; Hammad 2008; Dodge 2009, 2014a, b). Interestingly, the latest amphitheaters were constructed in the third and early fourth centuries CE, for example, at Beth Guvrin (Israel) (Dodge 2009), at a time when the gladiatorial games themselves were becoming far less frequent, and indeed late evidence does not survive in the West outside Italy. As combat displays declined, arenas continued to provide a venue for the other types of display with which they had long been associated – animal displays, acrobatics, and dancing. This continuity is very evident in the early sixth century CE writings of Cassiodorus and the contemporary diptychs of Constantinople (Cassiodorus *Variae* 5.42.6-10; Dodge 2009, 2011: 73–76; Dodge 2014a, b).

An Zhimin

Beichen Chen
Capital Normal University, Beijing, China

An Zhimin (1924–2005) was a successful Chinese archaeologist, who worked for the Institute of Archaeology, Chinese Academy of Sciences (known as "Chinese Academy of Social Sciences" after 1977), since the 1950s. His explorations into China's prehistoric cultures attracted much attention and made a major contribution toward creating a framework for the prehistoric archaeology of China (Gu 2014).

Biographical Information

An Zhimin was born in Yantai, Shandong Province, in 1924. He spent most of his childhood in Shandong and then went to Peking (known as "Beijing" from 1979) for high school study. At Yiwen High School 藝文中學 (known as "Beijing No.28 High School 北京第二十八中學" from 1952), an article by Liang Qichao 梁啟超 – *The Past and Future of Chinese Archaeology* 中國考古學的過去及將來 (Liang 1936) – awakened his interest in the field of archaeology.

During his undergraduate studies at the University of China 中國大學, An was able to study archaeology under the tutelage of a number of renowned scholars, such as Pei Wenzhong 裴文中 (1904–1982) and Torii Ryuzo 鳥居龍藏 (1870–1953). In 1949, he became a graduate student at Yenching University 燕京大學. After that he joined the Institute of Archaeology, Chinese Academy of Sciences, under Liang Siyong's 梁思永 (1904–1954) supervision, from where he began a career as an archaeologist that would endure for the next 50 years or so (An and An 2014).

Since then, a number of archaeological projects have been carried out under An Zhimin's management. During the 1950s and 1960s, he left his footprint in Hebei, Henan, Hunan, Qinghai, Inner Mongolia, and the three provinces in the

northeast of China. In 1978, he was appointed as the chief editor of the journal *Archaeology* (*Kaogu* 考古) and then as the director of the Neolithic Department of the Institute of Archaeology. In the following couple of years, he became first the deputy director of his Institute and then the chairman of the Department of Archaeology, at the Graduate School of Chinese Academy of Social Sciences. In 1986, An was conferred the title of correspondent academician by the German Archaeological Institute, and 5 years later, he was invited to be a visiting professor at the Institute for Research in Humanities, Kyoto University, Japan.

An Zhimin had expressed interest in China's Neolithic period from the beginning of his career, and he achieved great accomplishments in fields related to this. By defining the "Second Phase of the Miaodigou Culture 廟底溝文化," which lines up with the earlier Yangshao Culture 仰韶文化 in the west and the later Longshan Culture 龍山文化in the east, he argued that "the Yellow River region was undoubtedly the only origin of Chinese civilisation" (An 1987). This theory is also known as the model of "Central Plains diffusion." During the 1980s and 1990s, many scholars, such as Su Bingqi 蘇秉琦 (1909–1997), Zou Heng 鄒恆 (1927–2005), K. C. Chang 張光直 (1931–2001), Yan Wenming 嚴文明, Li Shaolian 李紹連, and others, were heavily involved in debate concerning the origin of Chinese civilisation. Their contributions have greatly enriched and deepened our understandings of the context of China's prehistoric cultures.

Anaerobic Conditions (Bogs, Waterlogged, Subaquatic): Preservation and Conservation

James A. Spriggs
Conservation Consultant, York, UK

Introduction

Archaeological artifacts which have been lost, abandoned, or deliberately deposited in the ground will become included in the natural cycles of decay and the return to nature. This normally results in the survival of only the more robust materials such as stone, shell, and ceramics and the partial survival of metals, glass, bone, and other inorganic materials. The most abundant materials used by mankind are of organic origin such as wood and plant materials, skins, and other animal products. These will normally all be destroyed through microbial activity and biodeterioration, leaving barely a trace. But occasionally these materials do survive, albeit in a greatly altered state, through becoming included in anaerobic waterlogged deposits. Where such conditions pertain, not only do a greater range of artifact materials survive but also environmental

macrofossil remains such as small bones, insect parts, plant remains, seeds, and pollen resulting from the interaction between humans and their immediate surroundings. Waterlogged archaeological deposits therefore represent a particularly valuable source of information about past cultures and environments, requiring special management and protection.

Definition

Anaerobic, or anoxic, conditions are formed by the exclusion of air from the burial medium through water saturation. This denies the microorganisms (mainly fungi and bacteria) responsible for biological decay the oxygen which their metabolism requires. These oxygen-free or "reducing" conditions can also provide excellent protection against corrosion for metals such as copper, lead, and iron whose normal corrosion is as a result of oxidation processes (Selwyn 2004).

Artifacts composed of organic materials (wood, leather, and animal and plant fibers) can survive burial in anaerobic deposits for many hundreds or thousands of years, but only if the artifacts become well sealed within anaerobic deposits and with their chemical equilibrium undisturbed and at a depth that does not permit exchange of oxygenated water from the deposit/air interface. Anaerobic waterlogged conditions most commonly exist in the sediments at the bottoms of rivers and lakes; in fenlands, marshes, and peat bogs; and in urban contexts where the natural water table is raised artificially through centuries of deliberate dumping of organic debris.

Key Issues/Current Debates/Future Directions/Examples

Wetlands have always been a focus of human activity and settlement, offering means for defense, transport, and trade or the ready availability of natural resources. Where anaerobic conditions persist into modern times, preserved cultural materials of many different types and sizes may be anticipated. Discoveries are almost always made due to modern exploitation, such as gravel extraction, peat digging, land drainage for agriculture, the dredging of rivers, and construction. Among the largest waterlogged wooden structures discovered in recent years are ships and large boats, normally discovered in silted-up river harbors and on riverbeds or incorporated into riverbanks. In the UK prehistoric dugout canoes are regularly found during gravel extraction in the floodplains of rivers or in the digging of drainage channels and artificial lakes. The remains of prehistoric settlements and associated trackways, constructed entirely out of wood, are often found accidentally or as a result of rescue excavations on sites threatened with the dewatering and shrinkage of overlying protective peat layers. Wetlands, especially bogs, can also contain remarkable assemblages of well-preserved artifacts of many material types, taken to be votive or sacrificial deposits. Bogs can also be the last resting places of human sacrifices, as in the case of the Danish bog bodies and Lindow Man (Stead et al. 1986), found during the commercial digging of peat. Culturally rich waterlogged deposits also exist in many ancient cities, such as London and York in the UK and the major ancient towns in Scandinavia. These highly organic contexts, sometimes referred to as "black earth," contain domestic, craft, and industrial waste, timber foundations, and environmental remains – all of which, when properly excavated and researched, can provide a highly detailed picture of the life and activities on that particular site and its surroundings, sometimes over many centuries.

Artifacts of organic origin can often be preserved sufficiently well that the surfaces still bear an extraordinary level of detail. Wood artifacts and structural timbers often bear the clear signs of the tools used in their shaping, allowing the type and size of the cutting tool to be identified. Even the "tool signature," the minute signs of damage and wear to the blade edge, can be recognized, allowing the use of the same tool to be identified over several timbers or within the same structure (Brunning 2010, 16). Non-artifactual wood from prehistoric contexts has occasionally been found still bearing the chew marks of ancient beavers (Coles 2006). The study of wood technology and biology often

provides valuable information relating to resource use and procurement, woodland management, and dating through dendrochronology. But despite appearances, waterlogged organics are usually to be found in a highly altered state upon excavation, having become denatured by their long period of burial. The more susceptible portions of the material's structural and chemical makeup will have been removed through processes such as hydrolysis, the breaking down of chemical bonds through the addition of water. This is partly driven by low levels of bacterial activity that is able to tolerate the toxic anaerobic conditions. Wood will lose its cellulose component leaving only the lignin skeleton, but enough of the macrofossil structure will often remain to permit identification (Kenward et al. 2008). Leather survives only because the tanning process has rendered the collagen fibers resistant to hydrolysis. Only textiles of animal fiber origin (hair, wool) are normally found, since keratin is similarly resistant. Other chemical factors in the burial medium may also have an effect on survival. Peat bogs can be strongly acidic, causing some materials, such as bone, to be destroyed. But peat bogs are also extremely tannin-rich meaning that skin products other than pre-tanned leather will become preserved. This accounts for the survival of "bog burials" where the human skin and some internal organs are well preserved, but the skeletal material has all but disappeared (Stead et al. 1986).

Such denatured organic materials are often structurally very weak and their surfaces in particular extremely soft and fragile, their shape only being maintained by the water that they contain. They are therefore very susceptible to drying from the moment of exposure onward, any loss of water content causing irreparable damage to both surface detail and whole objects due to shrinkage and structural collapse. Controlled archaeological excavations of waterlogged sites require special management and resourcing as the working conditions and anticipated results will be so different from a normal dry site. Special techniques and procedures will be required for uncovering waterlogged structures and artifacts, with specialist skills and knowledge available to undertake recording, sampling, and field stabilization and conservation (Brunning 2010). Advance plans need to be made for the safe packaging and temporary storage of recovered materials and arrangements made with suitable laboratories for longer-term storage and treatment. Advice on "best practice" on excavating fragile waterlogged organic materials is now available through European Standards (BS EN 16873:2016). The preservation treatment of waterlogged materials can be costly and complex, especially for larger items, and the decision to excavate and lift waterlogged structures and assemblages can only be presaged on the ability to undertake such preservation (Hoffman 2013). The possibility of reburial or "preservation in situ" has, it seems, only become a viable alternative in exceptional cases (Coles 1987; Spriggs 1987). Current research into these topics is reported to the triennial international meetings of the Waterlogged Organic Archaeological Materials (WOAM) Group of the ICOM Conservation Committee (e.g., Williams 2017).

The main threat to wetlands and other types of waterlogged deposits is from lowering of the water table, with consequent drying out, wastage, ingress of air, and the rapid onset of the normal processes of biodeterioration. In cities such as York and Bergen, evidence for dewatering can be linked directly to the construction of buildings with underground basement levels which serve as sumps for water from the surrounding cultural levels which start to dry out as a consequence. Rural wetland sites are under continual threat from activities such as sand and gravel quarrying, peat extraction, and field drainage for agriculture (e.g., French 2017). Recent research at the Mesolithic site of Star Carr, North Yorkshire, UK, has demonstrated just how damaging these threats can be when loss of waterlogging leads to changes in the site geochemistry (High et al. 2016). Waterlogged structures are seldom anticipated or detectable in advance of these activities, and major finds are not uncommon and have to be recovered by archaeologists under "rescue" conditions. Efforts at site protection are often most likely to succeed when in concert with other organizations with common interests such as nature conservation bodies and wildlife agencies. Legal protection is sometimes possible where cultural significance

can be established, and interest from other stakeholders, such as tourism and education, can also be valuable. But in most cases, some form of physical intervention will also be necessary to maintain or elevate the local water table. Where extensive structures, such as prehistoric trackways and lakeshore villages, are known to exist, various forms of environmental intervention to protect surviving portions have been used by, for example, constructing clay bunds around the area to be protected, which is then backfilled and artificially flooded (Coles 1987). These attempts at protection are usually costly and require continuous monitoring and long-term regular maintenance, if they are to be successful.

Research into new methods and strategies for site protection techniques is reported at regular intervals at the Preservation of Archaeological Remains In Situ (PARIS) International Conferences (e.g., Leuzinger et al. 2016). Important here is the development of techniques and equipment for inground monitoring to measure the rate of change in waterlogged soils and the effectiveness of remedial action taken (Smit et al. 2006). A number of site-specific projects are ongoing to find ways to slow down the deterioration of important waterlogged archaeological and historic structures and sites, such as at the Neolithic Sweet Track, Somerset, UK (Brunning 2000); Medieval Bryggen, Bergen, Norway (Mathieson et al. 2008), and in Medieval and later Amsterdam, The Netherlands (Klaassen 2005). These projects have led to an increasing awareness of the potentially catastrophic effects that could be caused by ongoing climate change.

Analogy in Archaeological Theory

Adriana Schmidt Dias
Department of History, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul (RS), Brazil

Introduction and Definition

An analogy is a cognitive process by which new phenomena are comprehended from known experiences, using the latter heuristically in building explanatory models and in directing future research. Analogies perform an important role in theory building and in suggesting new lines of research. An orthodox position in the philosophy of science posits that analogies are not indispensable in systematic scientific explanations (deductive-nomological model) and thus are not part of the process of theoretical justification (hypothetic-deductive model), that is, analogies are significant in the process of discovery but not when scientific justification is at stake because they function in the inductive confirmation of a given theoretical proposition. However, analogical reasoning can perform a clue role in the justification of hypothesis and theories, especially if we accept that scientific practice ultimately rests on analogical extensions of paradigmatic models. An analogical argument allows setting forth conclusions based on similarities between two or more entities that share relevant structural properties (analogues). Yet, an analogical argument is not exclusively based on similarities and coherences between analogues but on ideas, generalizations, and principles that make the analogical movement feasible and open to epistemic consideration (Shaw and Ashley 1983).

Key Issues/Current Debates

In the history of archaeological thinking, the epistemological role of analogical inferences, in general, and of ethnographic analogies, in particular, has been central in the ontological debate that has taken place in the last decades about the status of archaeological theory in the social sciences field. In epistemological terms, archaeological knowledge has always used analogies drawn from other fields, such as history (analogies about changes over long periods), paleontology (materialist analogies about the classification of evidences), biology (analogies about the interconnectedness of different types of natural phenomena), and, in particular, anthropology (analogies about cultural behavior) (Murray and Walker 1988).

Ethnographic analogies were foundational in prehistoric archaeology since the sixteenth century, when the contact with "contemporary savages" made possible in Europe widening

interpretative perspectives about ancient human artifacts, traditionally understood from a mythical or magical standpoint (Wylie 1985). The interpretations of antiquarians were configured as primitive analogies, that is, they were based on simple identifications and projections of certain empirical properties between two or more analogues, without even considering a relevant structural connection (Shaw and Ashley 1983).

The use of ethnographic analogies increased in the nineteenth century as attention was given to theoretical explanations of cultural development. If until the eighteenth century the antiquarian's perspective established a direct equivalence between "prehistoric primitives and moderns," for classical evolutionism, contemporary cultures were composed of different degrees of cultural complexity that were projected into the past as stages of a determined course of historical development. This first systematic use of analogies in archaeological interpretation posited that the most primitive contemporary cultures were presumably comparable to most ancient forms of prehistoric savagery. Such an idea took for granted an evolutionary starting point in a developmental sequence of technological, economic, and political stages leading to industrial civilization (Wylie 1985). Ethnographic analogies in classic evolutionary thinking were a direct reading of the past from the present. They were standard analogies in that the identification and projection of certain empirical properties between two or more analogues were constituted from conditions of relevance established by the very principles and theoretical structure that set them forth in the first place (Shaw and Ashley 1983). This kind of analogical inference is based on uniformitarian premises, making it impossible to prove its truth. Besides, they are prone to error and are a part of an ethnocentric, biased vision of the past (Wylie 1985; Trigger 1992).

A first reaction against the abuses of classical evolutionism stemmed from the rejection by culture-historical archaeology of ethnographic analogies as interpretative inferences about past human behavior. At the beginning of the twentieth century, the emphasis on establishing cultural typologies and chronologies championed by culture history led to a renewed appraisal of analogies based on the direct historical approach. In American archaeology, the proximity with anthropology made it possible to trace direct relationships between the prehistoric past and historical events documented in written sources. This was achieved by archaeological investigations in sites with contemporary occupations. As a result, archaeological contexts and styles from a given area were identified with groups that were recognizable in ethnohistorical sources. The analogical argument involved was based on continuous models of interpretation which imply that the sources of analogies presuppose a genetic connection between ascendant and descendant, in clear opposition with the purely functional connections so cherished by evolutionism. The direct historical analogies of the 1930s and 1940s implied archaeological tests that could correct or confirm hypotheses derived from ethnographic or ethnohistorical data. Archaeological tests helped to control analogies, and ethnographic data helped to stimulate and direct archaeological research (Wylie 1985; Trigger 1992; Willey and Sabloff 1996).

Given that most prehistoric phenomena do not have likely evolutionary descendants and that many documented ethnographic phenomena do not have any obvious archaeological ancestor, in the 1950s American archaeology began to search for new parameters for establishing general analogies based on discontinuous models of interpretation. Comparisons between the present and the past were filtered out by theoretical inferences derived from cultural ecology and multilinear evolutionism. Important in that regard was the notion that functional convergences between past and present cultures are mediated by similar environmental characteristics and similar levels of technological sophistication (Wylie 1985; O'Brien et al. 2005). They were, inferentially speaking, analogies with presumed structure, that is, analogies in which the connection between analogues is established by relevance, linking structure, and properties (Shaw and Ashley 1983).

At that time, it was held that the problem with ethnographic analogies was mostly related to the limitations of the sources. In order to overcome

such limitations, archaeologists should pursue their own ethnographic projects about continuous cultural change, by which living communities create, use, recycle, and discard the material culture that will eventually form the archaeological record (Wylie 1985). Although there was no methodological consensus about the role of analogies in archaeological interpretations, the term ethnoarchaeology began to be used from then on to define the research procedures of this "new analogy," placing emphasis on the study of subsistence and settlement patterns, production and use of material culture, and formation of the archaeological record. Experimental studies can also be included in this perspective because they were developed to document contemporary patterns of tool manufacture and the effects of natural processes in the formation of the archaeological record (David and Kramer 2001).

In the last three decades, the debate between processualism and postprocessualism regarding the role of analogies in archaeological interpretations reflects a wider epistemological discussion. The New Archaeology of the 1970s adopted a radical posture regarding ethnographic analogies. Such a posture stemmed from its explicit adoption of neopositivism, which rejects analogies as explanatory components of hypothetic-deductive methods. The New Archaeology strove to eliminate the dependence in analogies or any other form of inductive inferences leading to uncertain conclusions in hypotheses testing. They were treated as tautological inferences doomed to the fallacy of affirming the consequent. Such an objection was premised upon the limitations of amplitude and quality attributed to the empirical data used as referents of contemporary analogues, incapable of accounting for the diversity of past human behavior. The idea was that interpretative hypotheses must be deducted from nomothetic propositions based on well-established uniformitarian principles, such as those derived from natural sciences, projecting into the past human behavior regularities, limited to their biological and physical dimensions (Gould 1980; Gould and Watson 1982; Wylie 1985; David and Kramer 2001; O'Brien et al. 2005).

In the 1980s, the critique of the "safe yet limited" interpretations championed by processualism and of the role of analogies in archaeological practice led to the reassessment of the relationship between inductive methodologies and archaeological theory. If analogies are inductive but also ampliative, the conclusions they allow have more information than premises and initial data. The relevance of an analogy is assessed by analyzing the connecting principles between analogues that posit the simple presence or absence of given properties (formal analogies), emphasizing the importance of structural relationships between them (relational analogies). Relational analogies imply that causal mechanisms are behind similarities between analogues, determining the presence and interrelationship between properties. It is from this kind of analogical reasoning that established theories can expand to new analytical realms, given that such a reasoning is explanatory: the projection of new properties not only implies structural connections between the properties of the analogues but also explains their coherence (Hodder 1982; Shaw and Ashley 1983; Wylie 1985; O'Brien et al. 2005).

The analysis of the relational character of analogies between the present and the past in building archaeological theory is linked to the processualist revision of the guiding ontological principles of the discipline through middle-range theory and behavioral archaeology. Middle-range theory posited relationships between the static and the dynamic through inductive methodologies, while general theories would be devoted, instead, to understanding those processes involved in changes and diversifications of the organizational principles of living systems. For middle-range theory, all interpretative principles about past dynamics cannot be tested in the archaeological record, for it is static and contemporary. Inferences about the past can only be tested in actualistic studies, in which the formation of the archaeological record can be examined experientially and directly. Such an approach is also based on uniformitarian principles: the causes of current events leading to the formation of the static archaeological record are the same obtained in the past. An analogy allows setting forth

propositions about the past to be tested in the archaeological record. Consequently, ethnoarchaeology became a source for formulating and testing hypotheses about the relationship between cultural and material phenomena, making it possible to offer models of past societies based on contextual studies of the archaeological record (Binford 1977, 1981). To this analogical equation, behavioral archaeology adds noncultural processes that contribute to the formation of the archaeological record. It is argued that the understanding of the depositional and postdepositional processes responsible for the formation of the archaeological record is a means for refining analogical arguments linking past and present behaviors, as they are reflected in archaeological contexts (Schiffer 1995, 1996).

To the discussion on the limits of a neopositivist approach in archaeology, in the 1980s, postprocessual archaeology added a wider openness toward social sciences. The paradigmatic tensions between processual and postprocessual approaches at the end of the twentieth century are a part of a wider debate in human sciences about universalistic and particularistic perspectives, opposing materialist and symbolic visions of cultural phenomena. Postprocessualism, drawing from eclectic theoretical approaches, emphasizes the symbolic nature of material culture and its active role in the relationship among human beings and between them and the environment. It champions the importance of linking social practices to history, and by doing so, it aims to capture the gradual and cumulative processes of cultural maintenance and transformation. While processual analogies between the past and the present would entail external, nonparticipant visions in the study of human behavior (etic perspective), postprocessualism, by positing culture as a fabric of historically constituted meanings, seeks to understand the meanings of material culture by contextualizing it in particular symbolic environments (emic perspective). This led to a renewed discussion about the role of analogies in building continuous and discontinuous interpretative models about the past (Hodder 1986).

Future Directions

In current archaeological theory, these dichotomies have been relativized by understanding that the knowledge about the past is contingent to a network of dialectical relationships between the whole and the parts, the universal and the particular, the structure and the event, and the material and the symbolic. The role of analogies in processual and postprocessual ethnoarchaeological approaches shares the common goal of building, from ethnographic experiences directed by an "archaeological gaze," interpretative models about the relationship between practice and symbolism in the action of human beings upon the material world. Likewise, relational analogical thinking keeps feeding the development of ethnoarchaeological approaches strongly aligned with processualist premises, such as those arising from performance theory, and it also contributes to a dialogue with natural sciences through behavioral ecology and Darwinian archaeology (David and Kramer 2001; O'Brien et al. 2005).

Introduction

The theory of anarchism primarily concerns the organization of society in a way that fosters egalitarian or equitable forms of association and cooperation and resists all forms of domination. An anarchist perspective involves an awareness of, and critique of, how power is implemented through social relations, whether positively as in collaborative acts of mutual aid to common goals or negatively as in assertions of authoritarian power contrary to the interests of the community as a whole. As a theory concerning power and social relations, archaeologists apply anarchism for analyses of past societies, to interpret and evaluate forms of egalitarian or hierarchical relations, modes of domination or resistance, and expressions of control or autonomy. Moreover, it is not just for considering the past, but the theory can be applied to contemporary social arrangements concerning archaeology in multiple ways: how archaeologists organize themselves for research teams and field crews, involve local or descendant communities, or relate to the various publics concerning heritage. Anarchism has had an increasing influence upon archaeology in recent years, just as the theory has influenced other

disciplines throughout the social sciences and humanities.

Anarchism originated in the mid-nineteenth century, advocated by such individuals as William Godwin and Pierre-Joseph Proudhon. Anarchism concerns principles for the organization of societies without recourse to formal governments or centralized institutions. For this reason, the name of the theory translates as "no rulers": *an-* (without) + *arche* (ruler). However, a better translation of it is perhaps "without domination" or framed in active form as "against domination." Anarchism is a theory explicitly about human relationships without coercive forms of authority, hierarchy, or exploitation of other humans; many anarchists extend these prohibitions against domination even further to include human relations with nonhuman beings or entities, meaning other species and the environment.

This formulation, notably, is in contrast to popular notions about anarchy used in the sense of chaos. Rather, for its advocates, anarchism provides principles for social order among any group of people, even in contexts without centralized leadership. This notion provides a significant contrast to Hobbes' notion in 1651 concerning the need for a "Leviathan" to govern people that otherwise chaos would reign without a monarch or other dominant ruler and their enforcers. Instead, as the long history of human social and political organization indicates, peoples have generally organized their lives without the need for a king, monarch, or other leviathan to maintain order. Anarchists presume a degree of willingness to cooperate among consenting parties. Rather than chaos, anarchism is a theory about community-organized forms of social order.

To implement such social relations, anarchist theorists did not provide a blueprint for how societies should be organized, as they recognized that all peoples need to adapt their societies to meet their local historical situations and environmental circumstances. Anarchist theory instead consists of several values or principles for organizing people in egalitarian, equitable, and noncoercive ways, whether as small groups, local communities, extended networks, or societies as a whole. Common principles include individual and local group freedom or autonomy, voluntary forms of association and federation, mutual aid, decentralized and networked forms of organization, communal decision-making (direct democracy), temporary or situated forms of authority, direct actions, and resistance to all forms of domination or exploitation.

Shared among these principles is the emphasis on liberty and autonomy, freedom of thought and expression, both for individuals and groups. While there is a libertarian strain to this emphasis, they do not advocate for social atomism, where each person is left to care for oneself. Instead, there is a strong push for community relationships, although those should be engaged and pursued through voluntary forms of association and community agreement. Self-organization refers to the ability of individuals to organize cooperatively into groups at various scales for productive tasks or shared goals. According to anarchist notions, no central authority is necessary to accomplish any endeavor, no matter the scale. Mutual aid and cooperative endeavors are seen by anarchists as the core dynamic for the self-organization of groups and for the linking of those local corporate groups into larger community and regional networks of interaction. It's the practical needs of individuals within local groups that are the medium for organization. These repeated acts and engagements of mutual aid form networks that link individuals and groups in multifaceted manners that are nonhierarchical or decentralized in structure. Furthermore, these networks have a temporary quality, generally lasting for the duration of utility for those involved; there is a general opposition to arrangements becoming fixed or entrenched, which are limitations upon the freedom of individuals and groups.

While building connections – mutual aid and alliances – are something anarchists support, concentrated authority is something they oppose. Historically, much of anarchist discourse has been directed foremost at the state, as a political formation that is hierarchical and uses state power to enforce and maintain hierarchical relations. However, archaeologists are concerned with the application of power within all types of societies, whether states or non-states. To apply to all

societies and settings, the emphasis therefore is upon assertions of domination in any social setting. Various forms of absolutism can occur at multiple scales of human social interaction.

Central to anarchist thinking is that it is a theory about power. For this reason, anarchists have shaped thinking about social power in the social sciences and philosophy, influencing Nietzsche and Foucault. This is founded on the basic point made by Bertrand Russell (2004 [1938]) that the natural sciences are about the physical dynamics of energy, while the social sciences are about the dynamics of human social power. As archaeology increasingly uses the language and reasoning of the natural sciences (as it should), archaeologists need to also deploy theoretical frameworks about social power, and early anarchist theorists have been at the source of that.

Anarchist approaches have much relevance for archaeologies, especially for social or political perspectives that must understand the dynamics of power relations. Since the vast majority of societies in the *longue durée* of human history have been anarchies, or societies without formal governments or centralized institutions, the theory of anarchism has relevance for understanding the self-organization of communities.

The theory has more than application toward interpreting the archaeological record, however. Due to its basis as an analysis and critique of power, the theory also applies as well to the contemporary context of archaeology and its practices. Power pervades all forms of social relations that lead to coordinated forms of action. For this reason, anarchism can be applied to the contexts of archaeological work as field crews, as researchers collaborating with communities, as workers in Cultural Resource Management firms or cooperatives, as educators in the classroom, as stakeholders regarding heritage, and so on across the many arenas in which archaeologists relate to others.

Historical Background

Anarchism has a long history in Western discourse, extending back to the mid-1800s. Yet, anarchist principles for social organization associated with the theory have found expression in numerous societies and groups that extend back millennia. Some historians connect such principles with the Taoists, Gnostic groups, and even early Christianity. In this way, anarchistic societies, if not anarchist (meaning derived from the discourse of anarchist thinkers), have been expressed throughout human history. In several respects, anarchist elements form a part of any society, non-states or states, since all societies contend with issues of centralization and decentralization, hierarchy and egalitarianism, and control and autonomy.

One of the earliest formalizations of anarchist thought derives from William Godwin, who in 1793 published *Enquiry Concerning Political Justice, and its Influence on General Virtue and Happiness*, offering how an anarchist society might be organized. Shortly thereafter, in 1798, Immanuel Kant defined anarchy as a form of government entailing law and freedom without force in *Anthropology from a Pragmatic Point of View*. The term became most prominent decades later with Pierre Joseph Proudhon's 1840 publication of *What Is Property? An Enquiry into the Principle of Right and of Government*. Significant subsequent thinkers included Peter Kropotkin and Mikael Bakunin in Europe and Emma Goldman in the USA. Unlike Marxism, which can be distilled, as its name implies, to Marx, anarchists rely upon a plurality of thinkers, each of whom provides a unique vantage point to think through human sociopolitical dynamics. Not one of those thinkers could be pointed to as central, as Marx is to Marxism.

These two traditions share a history. Both are traditions of the political left. Both aim for an egalitarian society and profess interest in an ultimate society of communism without a domineering state. Both joined in efforts of uniting laborers beyond countries in the workers' internationals. Advocates and thinkers of both Marxism and anarchism engaged in vigorous discussions and debates, with Marx enthusiastically meeting Proudhon and Bakunin at various times, even if he later turned against them theoretically. Despite the closeness of being both political allies to the left

of Liberalism, the two also differed on how best to transform society. For Marxism, revolution proceeds in stages, and the workers need to take over state authority in order to enable the eventual transformation into communism. Anarchism, on the other hand, requires that liberation proceeds in a manner that reflects the end goal. Anarchists rejected centralization of the state-level authority from the outset. This grew from the anarchist idea that societies are prefigured, which is to say they emerge from the practices that create them. Instead of the ends justifying the means, anarchists believe that the means create the ends or that the means are the ends – the two are simultaneous. Therefore, while they were close politically, the issue of centralization of power in their methods caused a fissure between the groups. Marx's ideas gained stronger adherents, in the decades following the fissure, both in state and academic positions. This is also reflected in the predominance of Marxism in academic discourse since. However, in recent years, anarchism has seen a resurgence of application.

In the late nineteenth and early twentieth century, interest in anarchism would increase with theorists such as Elisée Reclus, Gustav Landauer, Errico Malatesta, and Voltairine de Cleyre, among others. In many quarters, other major thinkers are regarded within the scope of anarchism, such as Max Stirner or Leo Tolstoy. Into the later twentieth century, the theory of anarchism further developed through Rudolph Rocker, Colin Ward, Noam Chomsky, and Murray Bookchin, among others. Recently, theorists have also adapted anarchism in light of its affinity or relevance to postmodern and poststructuralist thinkers such as Foucault, Derrida, and Lacan (e.g., Newman 2001).

In anthropology, there have been several scholars that have used anarchism to assess cultures throughout the world. Most notably, Pierre Clastres (1987), in *Society Against the State*, has argued that anarchistic societies have not developed a political centralized state but rather that they explicitly do not aim to concentrate power in their societies, preferring the autonomy of groups. Harold Barclay (1982) has provided a survey of anarchic societies with *People without Governments*. Brian Morris (2014) has emphasized the affinity of anarchism and the discipline of anthropology overall, as both emphasize local cultural and historical contexts and relay the diverse possibilities for arranging human societies. While there have been important precursors, it is with the work of James C. Scott and David Graeber that anthropologists have increasingly begun to apply anarchist theory. James Scott (2009) has provided a historical ethnography of societies that oppose the state in Southeast Asia, and his overall works have often been about "arts of resistance" to domination across numerous cultures. The work of David Graeber (2004) has influenced anthropologists and other social scientists toward the breadth and scope of anarchist perspectives, whether upon exchange, debt, democracy, and much more.

Anarchist archaeologists have become more prominent in recent years, including Severin Fowles' (2010) study of a "People's History of the American Southwest," Angelbeck and Grier's (2012) analysis of the archaeological history of the "inverted pear"-shaped social structure of the Coast Salish of the Pacific Northwest Coast, and James Flexner's (2014) treatment of the archaeology of states and non-states in Hawai'i and Vanuatu. Three doctoral dissertations concern anarchist analyses, including our own work (see further readings). Colleen Morgan (2015) has published an overview of anarchist analyses in archaeology. Others have dealt with anarchist analyses implicitly or tangentially, such as Wengrow and Graeber's (2015) discussion of the shifting modes of sociopolitical orders from hierarchy to heterarchy prior to the development of states or Gonzalez-Ruibal's (2014) archaeology of resistance in the borderlands of Ethiopia and Sudan. The basic premises of an anarchist archaeology have been outlined in "Foundations of an Anarchist Archaeology: A Community Manifesto" (Black Trowel Collective 2016).

Anarchist archaeologists often recognize that other scholars tread similar ground, emphasizing order without governments or centralization, recognizing shifting or temporary forms of authority, or acts of resistance in response to forms of domination. These could be called anarchistic studies

in that they parallel anarchist interests without explicitly naming or drawing upon anarchist theory. For instance, McGuire and Saitta (1996), while generally using a Marxist dialectical perspective, emphasized how groups in the Pueblo Southwest can arrange and exhibit both egalitarian and hierarchical sociopolitical formations (i.e., it is not a simple either/or dichotomy). This parallels anarchist views on the complexity of egalitarian forms of social organization and aspects of resisting domination. Barbara Mills (2004), in "The Establishment and Defeat of Hierarchy," argued that forms of hierarchy were contested through the destruction of the material signatures of ritual expressions of inequalities. Finally, Robert L. Bettinger's (2015) *Orderly Anarchy* presented a study of indigenous California cultures that concerned their general social order in the absence of government that also parallels anarchist themes without drawing upon anarchist discourse. A close association also exists with works in heterarchy, whereby Carole Crumley (1995) and others have emphasized the presence of complex nonhierarchical societies. The theory of heterarchy reveals the possibilities for numerous authorities in a society or nodes in a network, allowing for more complex and dynamic interactions and information flows. Many societies, formerly viewed as simply egalitarian, are more accurately heterarchical with their authorities, revealing the diverse ways that cultures can arrange their social relations.

Key Issues/Current Debates

> The epic poems, the inscriptions on monuments, the treaties of peace – nearly all historical documents bear the same character; they deal with the breaches of peace, not with peace itself. So that the best-intentioned historian unconsciously draws a distorted picture of the times he endeavors to depict; and, to restore the real proportion between conflict and union, we are now bound to enter into a minute analysis of the thousands of small facts and faint indications accidentally preserved in the relics of the past; to interpret them with the aid of comparative ethnology; and, after having heard so much about what used to divide men, to reconstruct stone by stone the institutions which used to unite them. (Kropotkin 1955 [1902]: 117)

Over a century ago, Peter Kropotkin (1955 [1902]) outlined an important role for archaeology in providing a counter-ballast to the historian's emphasis on conflicts and changes in the chronology of the past and instead highlighted that the great bulk of time consists of the alliance of people in constructive relationships and that archaeologists can help "reconstruct stone by stone the institutions which used to unite them." Archaeological chronologies, too, are flush with terms that emphasize not only periods of change but also periods in which domination was at its peak: "classical," "formative," or "climax" periods are typically identified as cultural "fluorescences." Through such language, other periods are seen as lesser in cultural achievement, with periods of "cultural decline," "dissolution," "de-evolution," or "collapse." Anarchist theory, with its focus on power and a critique of political structures, can offer alternate insights into these periods. Instead, these may represent popular assertions of local sovereignty or actions to achieve less hierarchical social arrangements, for instance. Traditional archaeological chronologies are turned on their heads when reframed using anarchist theory and its consideration of power relations.

Anarchists view all human social relations as mediated by or influenced by power relations. Anarchist approaches also entail an understanding of the dual role of power, as a force for domination as well as a force for voluntary alliances. Power relations, instead of necessarily dominating or hierarchical, can also be built on mutual cooperation, equity, and egalitarianism. The former power represents "power over" another person, which anarchists refer to as "vertical power." This is top-down form of power, as a boss to an employee, a general to a soldier, and a king to its subjects. The second form of power anarchists recognize is "horizontal power." This is the power to organize in alliances. It is a bottom-up form of power, as with marches, unions, and many grassroots social movements.

Anarchists argue that an emphasis in our language usage upon vertical forms of power can be disenfranchising and marginalizing. Horizontal forms of power must be considered as a power that can oppose vertical forms of power.

Therefore, archaeologists aim to assess not only "traditional" forms of power that are hegemonically used to dominate others but also the multiple forms that engender voluntary alliances between people.

The following key issues for anarchist archaeologies involve an assessment of power in past or contemporary social relations or within modern disciplinary practices. Whether vertical or horizontal, power often is distributed through authorities. Bakunin (1953 [1871]: 239) referred to this distinction as between natural and artificial authority. The former is justified as an expression of natural human relationships, whereas artificial authorities are imposed through institutional structures. Saul Newman (2001: 38–41) considered this distinction significantly important in political philosophy. No longer could one critique the anarchists for an oversimplified focus upon the state, since an anarchist conception of power is not tied solely to the state or the "social contract," but instead concerns the power dynamics of any human social relationship (Newman 2001: 40).

While anarchists oppose authoritarian power, they do not reject authority in itself. Bakunin (1953 [1871]: 253–254) stated "I bow before the authority of special men because it is imposed upon me by my own reason. Therefore there is no fixed and constant authority, but a continual exchange of mutual, temporary, and, above all, voluntary authority and subordination." Therefore, any authority must be situationally justified. This notion of justification also applies to any social arrangement as well, such as an alliance, exchange relation, or network. Once the need for an alliance accomplishes its goal or outlives its need, a union might soon dissipate to return greater autonomy to local groups. These distinctions provide archaeologists a way to consider expressions of authority, alliances, or other social arrangements in the past as either imposed or consensus-based. Historical processes in any society's culture history may reveal tensions regarding the centralization and contestation of power, either diachronically or synchronically. The changing nature of these community relationships can reveal themselves in settlement patterns, community arrangements, or households, exhibiting decentralized or centralized characteristics. For instance, in many anarchic societies, authority is not centralized. Rather, it consists of numerous authorities that provide balance to each other and a multivocal, diverse environment of thought and practice. This type of heterarchical structure is very resilient (Crumley 1995).

These distinctions between natural authority and artificial authority also apply to contemporary practices since archaeologists represent ourselves as authorities to others concerning the narratives of the past or the management of heritage. Archaeologists should aim to be natural authorities concerning the past, as people knowledgeable of our conceptions of past cultures and events, or as individuals trained in archaeological methods as a craft. Yet, archaeologists should not become artificial authorities, those imposing their authority over stories of the past, as there can be multiple narratives, particularly those of indigenous oral traditions. As well, this applies to stances regarding heritage of sites and artifacts, where the need of scientific study of heritage is claimed over the interests of other publics, especially descendant groups with non-research interests at stake. The anarchist division of types of authority enables and promotes a multivocality regarding heritage while simultaneously allowing for our expertise regarding our craft. Indeed, this may provide solid footing for engaging other publics and communities regarding archaeology.

Anarchist theory supports that we can engage these publics, both descendant and non-descendant communities, as natural authorities regarding our craft and specialization and yet recognize the multitude of other authorities regarding the heritage and narratives of the past. This contributes to a more inclusive and collaborative archaeology, resulting in changes in field methods, publication practices, and interpretive stances. An anarchist archaeology offers support to such archaeologies with its emphasis in the decentralization of authorities, the formation of alliances of mutual interest, and an equality of representation among numerous publics.

Anarchist critiques of power and authority bring many ethical implications for implementing anti-authoritarian practices. These stances, concerning authority and assessments of power relations, extend to anarchist approaches in education concerning archaeology. Pedagogy, accordingly, is not a place for hierarchical forms of knowledge dispersal but a setting for engaging others in a shared process of learning, whether in the classroom, at a site with a field school, or in public talks.

An anarchist assessment can also be brought to bear on other forms of social arrangements in archaeological practices, such as research teams, field crews, or archaeological firms. These allow for considering the justification of certain hierarchies or their appropriateness for the tasks at hand. They may ask whether certain interpretations are dominant regarding publication of results or reports or whether recommendations for heritage management adequately reflect the consensus of interests involved.

The interests of anarchist archaeologies share much with other strains of archaeology. These affinities include those emphases on activist archaeology that aims to transform existing practices for the betterment of communities. In the critique of dominant structures, there are shared emphases with archaeologies of resistance (e.g., Ruibal-Gonzalez 2014). This certainly extends to parallel aims of decolonizing archaeologies that aim to critique and remove colonial structures of domination over indigenous peoples and their heritage. To address such structures and pursue alternate forms of social relations with indigenous or descendant groups is a primary method to address such goals. This is supported by anarchist emphases on equitable relationships and direct actions to prefigure the associations that will enable a better community. In this way, anarchist archaeologies also buttress the aims of subaltern archaeologies to redress structures of dominance, including both feminist and indigenous archaeologies. A final example of concurrent aims is with Marxist archaeologies. While there has been a long history of debate between advocates of both approaches, the shared aims of a more equitable society and a critique of power structures in society is present in both. The end goals are similar as well. In many ways, anarchist and Marxist archaeologies are sisters that have been too long separated. Indeed, the many parallel and contradictory perspectives provided by these two perspectives only enhance both archaeologies in their efforts.

In summation, anarchist theory, based in over a century of debate and refinement, both among anarchists and in dialogues with Marxists and others of the left and right, has developed a critique of hierarchical power relations as well as proposals for enacting more equitable relations. In this way, anarchists offer varieties of social and political archaeology that center on the dynamics of power relationships, and these can be applied to the societies of the past and to relationships in the present.

Anatolian Historic City Centers: Urban Archaeology in Multilayered Context

Burak Belge
Faculty of Architecture, Department of City and Regional Planning, Mersin University, Mersin, Turkey

State of Knowledge and Current Debates

Anatolia (Asia Minor) as a cradle of first settlements is a land bridge between east and west, but not a single geographical corridor (Sagona and Zimansky 2009, 1). Varying materials and latter agricultural production caused the emergence of first settlements in especially central and southeastern Anatolia. Although there was a complex culture, making pottery and stone workmanship at Göbeklitepe as a cult centre (?) dated nearly 10.000 BC (Schmidt 2012, 87), which could not be defined as a settlement or city. However, there are first examples of round houses in the southeastern Anatolia settlements as Hallan Çemi dated approximately 11,000 BC (Rosenberg 1999, 359). In central Anatolia, Çatalhöyük (Hodder 1996, 43–46) and Aşıklı Höyük (Esin 1996, 31) are the first examples of flat-roofed and adjacent houses let to cultural interaction and daily-life production together. These were first examples of settlements with a communal life instead of a division of labor or social stratification. But, by the time, transformation of houses and changes in structure would be followed in unique settlements like Çayönü, where rounded houses had been turned into rectangular units (not only houses but also other specific uses like cult centers and open spaces) in a 3000 years from 8000 BC to 5000 BC (Özdoğan 1999, 317 and 1996, 21). Then, Anatolia let to settlements with its own resources and a junction for various trading materials from surrounding area including Mesopotamia, Mediterranean, Aegean and Black Sea and Thrace (Europe). Therefore, there have been always varying size settlements in different context and characteristics or even the capitals of different cultures and civilizations in Anatolia. The first one is Hattusa, the capital of Hittites that were first Anatolia centered Civilization on the arc of Halys River in 2750 BC (McEvedy 2004, 24), and the last capital is Ankara that is a multilayered city has been continuously occupied since Phrygians around 750 BC. In sum, there are different settlement patterns and cities, not only by geographical or natural conditions but also by cultural interaction, trade, war, or mass migrations. The cultural and historical accumulations of various cultures and their socio-spatial development throughout history have pioneered numerous archaeological sites in contemporary Anatolia. Some of them like Troy or Miletus were abandoned by natural causes such as earthquakes or alluvial accumulation or man-made influences like wars. On the other hand, most of the settlements-cities have been permanently settled since early ages and still inhabited ones are defined as multilayered settlements (Bilgin Altınöz 2002). In other words, most of the historical cities have multilayered features with archaeological stratification behind modern life. In fact, not only physical archaeological stratification but also cultures, memories, traditions, rituals, and sometimes functions have accumulated in historic urban centers. In fact, each contemporary settlement or archaeological site has different layers or periods of settlements since its inception but multilayered settlements contain subsoil archaeological strata embedded in everyday life as vertical and horizontal layers. In this entry, multilayered historic city centers in Anatolia are presented with key features and interesting spatial context, then a method to evaluate archaeological potential of multilayered settlements as subzones is underlined.

Multilayered Historic City Centers in Anatolia

According to the recent official record, there are registered 16,706 archaeological, 288 urban conservation, 170 historical, 33 urban archaeological, and 88 mixed conservation sites in Turkey. In addition, 359 conservation areas overlaid with natural conservation areas (http://www.kulturvarliklari.gov.tr/TR,44973/turkiye-geneli-sit-alanlari-istatistikleri.html, accessed in September

2018). In addition to national official records, 16 cultural and two mixed sites, recently Göbeklitepe (2018) are listed in UNESCO, World Heritage List (http://whc.unesco.org/en/statesparties/tr, accessed in September 2018). Four of cultural sites, İstanbul, Bursa, Pergamon, and Diyarbakır Fortress-Citadel, which are still inhabited as modern cities, include multilayered features referring their cultural accumulation. In addition to sites in World Heritage List, there are 77 sites in varying contexts in the tentative list of UNESCO (http://whc.unesco.org/en/tentativelists/state=tr, accessed in September 2018). From that list, Alanya, Çanakkale (Dardanelles), Hacı Bayram Mosque and its surrounding area in Ankara, İznik (Nicaea), Konya (Iconium), St. Paul Church, St. Paul's Well and surrounding historic quarters in Tarsus, The Bodrum Castle in Halikarnassos, Tushpa/Van Fortress-the Mound and the Old City of Van, Yivli Minaret Mosque in the old fortress of Antalya and Zeynel Abidin Mosque Complex and Mor Yakup (Saint Jacob) Church-Mardin in tentative list include some references for multilayered context.

However, the multilayered potential of Anatolia is not limited with UNESCO's lists. In an alphabetical order according to modern names, Adana (Tepebağ tumulus – Antiochia on the Sarus), Ankara (Ankyra), Antakya (Antioch on the Orontes), Antalya (the Citadel), Bergama (Pergamon), Bodrum (Halicarnassus), Bursa, Çanakkale (Dardanelles), Diyarbakır (Amida), Edirne (Hadrianopolis), Foça (Phokaia), Gaziantep (Antiochia ad Taurum?), İstanbul (Constantinople-Byzantium), İzmir (Smyrna), İzmit (Nicomedia), İznik (Nicaea), Kayseri (Caesarea in Cappadocia), Konya (Iconium), Manisa (Magnesia ad Sipylum), Mardin, Milas (Mylasa), Side, Silifke (Seleucia on the Calycadnus), Sinop (Sinope), Şanlıurfa (Edessa), Tarsus (Antiochia on the Cydnus), Trabzon (Trebizond), Urla (Klazomenai), and Van (Tuspa) are well-known multilayered settlements of Anatolia, which have been continuously inhabited since early ages. In other words, multilayered historic city centers of Anatolia include cosmopolitan cities or capitals, forgotten centers of antiquity and small towns together with ongoing modern life. Detailed data and updated reports about those multilayered settlements, where there are ongoing or recently completed archaeological researches, would be found at the official website of the General Directorate of Cultural Assets and Museums as annual e-books of Symposiums (in Turkish) (http://www.kulturvarliklari.gov.tr/TR,44758/e-kitap.html accessed in September, 2018). In any case, discussing whole of them in same detail is a hard issue for a single paper. However, for selected multilayered historic city centers in different context, brief history, known monumental or conserved archaeological remains, physical traces of multilayered structure and socio-spatial continuity of life are concise to describe the term of multilayered in the following text.

İstanbul: The Capital of Three Empires

İstanbul has a strategic geographical location between Europe and Anatolia and has a perpetual role as the capital of Eastern Roman Empire (later Byzantine) and the Ottoman Empire. The Archaeological Park including monumental and administrative buildings of Romans and Ottomans at the horn of the Historical Peninsula with the Suleymaniye quarter, the Zeyrek area of settlement and the Theodosian land walls were listed in UNESCO World Heritage List in 1985. In fact, not only listed sites, the Historical Peninsula includes accumulation of archaeological layers merged with modern life. Özdoğan (2013, 4) underlines that the depth of archaeological deposits might reach 32 meters in the Historical Peninsula. Salvage excavations at the Yenikapı Project for Metro and Light Rail Systems (Marmaray Excavations) indicate an Early Neolithic settlement dated between 6400 BC and 4800 BC below the sand deposits of the Port of Theodosius, which was the largest commercial centre of Constantinople (Özdoğan 2013, 4). Tuna (2003, 89) said that there are various archaeological remains and ad hoc findings indicating subsoil archaeological potential in whole peninsula and the boundaries of old ports are known. In addition to archaeological findings, as a multilayered socio-spatial continuity, the ancient route of Mese (Middle Route) starting from the Milion

(mile stone) between the Hippodrome and the Hagia Sophia to the Golden Gate through Constantine's Forum, Forum Tauri, Forum Bovis, and Forum of Arcadius is still observable in contemporary İstanbul. The spine of Divan Yolu (the route to governmental structure of Ottoman Empire) from the square of Sultanahmet to Çemberlitaş, then the Square of Beyazıt lay on the ancient route of Mese. Brief information and related documents are available in İstanbul at UNESCO website (http://whc.unesco.org/en/list/356 (accessed in September 2018)). In fact, as a multilayered historic city centre of Istanbul with a population of approximately 15 million, the Historical Peninsula endangered with urban development pressure and infrastructure needs. Therefore, unfortunately, archaeological potential of the Peninsula could not be integrated to modern life and presented to public for increasing feeling of multilayeredness.

Ankara, Ankyra: An Ancient and a Modern Capital

Ankara, capital of the Republic of Turkey, had been centers of different civilizations because of core location in Anatolia. Surveys (Kadıoğlu and Görkay 2007) indicate that Ankara established near to Hacı Bayram Hill by the Phrygians because of defense advantages. The hill was probably used the temple for Cybele, the chief goddess of Anatolia. In Roman period, Ankara as the capital of Galatia was embellished with many monuments, and the Temple of Augustus, Roman Baths, Theatre, colonnaded roads, and the Column of Julianus. Furthermore, inscriptions indicate other monumental structures like Stadion, Nymphaeum, and Palatium (Kadıoğlu and Görkay 2007, 21). Ankara had conserved its central role during the Ottoman Period with commercial activities (Çağlayan 1999, 38). After the Ottoman Empire, Ankara was planned as the capital and the characteristics of the old city was carefully conserved until the mid of twentieth century (Tankut 1993, 79). However, the historic core has numerous development operations especially along main routes since 1950s. Todays, just monumental structures are observable in low conditions. The Palestra and Roman Bath are conserved as open-air archaeological museum, but the level of conservation and site-presentation features have to be revised. In fact, according to socio-spatial continuity of Ankara, two sites have to be discussed to get multilayered context. At the hill, where the city was established, the Temple of Augustus (Monumentum Ancyranum) dated first century AD and Hacı Bayram Mosque dated fifteenth century are conserved together those indicating multilayered continuity of site as a holy place. According to archeological studies, there are known traces of Phrygian Temple or earlier sanctuary at the same area (Fig. 1). The second one is probable location of Roman Forum, according to main routes, junctions, and columns (Fig. 2), has been still sustained its role as administrative core of modern capital, where the Governorship of Ankara has been located in the same square.

İzmir, Smyrna: The Western Gate of Anatolia

The multilayered historic centre of İzmir, Smyrna, was founded between the Mount Pagus (Kadifekale in Turkish) and the coast in the Hellenistic Period (Cadoux 1938, 10–11). In ancient times, Roman Period was the most brilliant times of Smyrna. There are writings indicating Smyrna's beauty like Strabo's, the geographer, says of it *"…And now is the most beautiful of all the cities"* (Cadoux 1938, 171). Smyrna's history in Byzantine Period is not known very well but the fortification might be a priority for city like other Anatolian Cities. The city had an important role in Christian World by becoming one of the metropolite centers in 692 (Kuban 2001, 61). In the Ottoman Period, İzmir become a crucial commercial centre in Mediterranean. At the beginning of twentieth century, there were political and economic problems and in 1914, the First World War stopped commercial activities of İzmir with European countries. In Early Republican Period, the rehabilitation and reconstruction of city was the most important problem for historic city centre (Belge 2012, 338). Agora, the Mount Pagus (Acropolis) and Theatre, where there are ongoing archaeological researches (http://www.antiksmyrna.com/Default.aspx accessed in September 2018) are monumental and seen

Anatolian Historic City Centers: Urban Archaeology in Multilayered Context, Fig. 3 Open bazaar on Roman Road in İzmir (Smyrna). (Personal archive of the author)

archaeological remains of the city, which indicate significant archaeological potential of Roman times. In addition to them, a well-conserved Roman Road is still used as an open bazaar (Fig. 3). In any case, main characteristics of multilayered structure of İzmir would be followed through recent urban pattern. Especially the zone between State Agora, the Mount Pagus (Acropolis), and Theatre has been continuously occupation since at least 324 BC should be evaluated another type of multilayered heritage, pattern, and axes. Although the zone was seen as low occupation area in the Byzantine Period, there had been Turkish quarters in the zone until the beginning of Early Republican Period. The Eşrefpaşa and Anafartalar Avenues defined the western and northern boundaries of the zone. The probable route of the ancient fortification wall defined the eastern boundary of zone. There are some conserved pieces of fortification walls in Altınpark Street. In that area, there is no complete destruction by modern developments, because there are traditional and 1–2 floored buildings, which probably do not have basement (Belge 2005, 136). Gridiron axes that was a symbol of Hellenistic era in Anatolia will be still observable by aerial photographs or base maps (Fig. 4). Therefore, urban archaeological potential of İzmir is not limited with just archaeological remains, streets, and historic axes have to be conserved as archaeological heritage, especially against large-scale urban regeneration projects. In a similar context, another historic ax defines the arc of the ancient inner port, Anafartalar Street, known as Kemeraltı Arc. The zone has been settled continuously since alluvial floods filled the ancient port completely in the beginning of the eighteenth century. Kemeraltı Arc has been the centre of traditional commercial activities (Belge 2005, 143). In the present, traditional buildings lay on conserved traditional pattern of the nineteenth century. Todays, the zone

Anatolian Historic City Centers: Urban Archaeology in Multilayered Context, Fig. 4 Grid-iron axes (observed from base map or estimated) in the zone between Agora (indicated as Zone 1), the Mount Pagus (Acropolis), and Theatre (Belge 2005, 136)

conserves vitality and variety of an ancient port with functions, goods, ethnicities, and contemporary life together (Fig. 5).

Antakya, Antioch on the Orontes: *"Orientis Apicem Pulcrum"* (The Queen of the East)

Similar to İzmir (Smyrna), multilayered features of Antakya are observable through recent urban pattern as streets and axes following Hellenistic gridiron plan of the city. Morey (1936, 651) points out that Antakya is one of the four metropoles of the Later Empire with Rome, Constantinople, and Alexandria. The city was established at the junction of Anatolia, the Levant and northern Mesopotamia and the fertility of Amik Valley and Orontes flourished it. In the Hellenistic Period, there is a well-known grid-iron plan between the Mount Silpius and Orontes let probably new residential areas for increasing population, which had increased from 25,000 to 400,000 (Downey 1963, 30–33 and 1958, 87). Antioch history is marked by a series of catastrophes particularly earthquakes and streams overflowing, which led various damage by raising the ground level. Since third century BC, the ground has risen 11 m in the axis of the city; the stratum representing the second Byzantine conquest of the tenth century AD is on the average 4 m below the present ground level, that of the reconstruction under Justinian 7 m, and that of the Monumental Roman Street 8.5 m (Tuna and Belge 2011). However, aerial photographs and basemaps have revealed the Hellenistic gridiron plan traced in the modern street layout hidden under the traditional urban pattern. Colonnaded main route (Cardo Maximus) is still observable as the main street of historic city centre of Antakya, as Kurtuluş Street (A at Fig. 6), Hippodrome, Theatre, and Baths (B-C-D at Fig. 6) had been documented by archaeological researches in 1930s (Morey 1936, 638).

Anatolian Historic City Centers: Urban Archaeology in Multilayered Context, Fig. 5 The arc of the ancient inner port, Anafartalar Street, known as Kemeraltı Arc and infilling area (Belge 2005, 143)

Furthermore, recent researches (Leblanc and Poccardi 1999; Uggeri 1998) indicate correlation between Hellenistic gridiron patterns with recent street pattern. Especially, if Uggeri's (1998) map is georeferenced with current base-map and aerial view, the multilayered characteristic of Antakya could be followed in contemporary city (Fig. 7).

Pergamon and Its Multilayered Cultural Landscape

As another example of glorious Hellenistic art and planning, Bergama (Pergamon) is listed as a special site with the term of "multilayered" in whole UNESCO World Heritage List. The characteristics of Bergama (Pergamon) is emphasized as the achievements of the civilizations from Hellenistic, Roman, Byzantine, and Ottoman Periods and so reflecting different cultural features together (http://whc.unesco.org/en/list/1457 accessed in October, 2017). The multilayered development of Pergamon was comprehensively studied and published (Bilgin 2002; Bilgin et al. 2016). As another multilayered feature, cultural rituals related with sacred springs at Asklepion still sustaining by local groups. In Turkey, "Henna Night" is a ritual at the beginning of wedding like other eastern countries and local people of Bergama have been still used holy waters of the springs at Asklepion to clean-wash bride's hands after "Henna Night." Although the Asklepion has been conserved as an open-air Archaeological Museum entered by ticket, the families of bride and groom have forced the guards of the Ministry of Culture and Tourism to let them to enter the site to complete their rituals (Fig. 8).

Tarsus, the City of Cleopatra, and Mark Antony

Tarsus, where it is possible to mention about an ongoing settlement and multilayered stratigraphy from Neolithic Ages to recent town. Archaeological researches (Belge 2016; Gök and Belge 2016) indicate a settlement pattern starts from Gözlükule

Anatolian Historic City Centers: Urban Archaeology in Multilayered Context, Fig. 6 The location of main features of Antioch on map of Morey (1936, 638). (Prepared by the author)

(a prehistoric mound at the south of centre) and enlarging to northern area and the eastern bound of Kydnos River. Similar to aforementioned ones, in Tarsus, there are monumental structures and seen archaeological remains around historic city centre. Roman Road in the core of Tarsus that is seen as a crucial problem waiting for a clever site management solution to avoid obstructing the vehicular and pedestrian circulation system for nearly two decades and to create an archaeological focus. Another monumental archaeological remain is Donuktaş, which is a Roman Temple (approx. 43 × 100 m), dated to the Late Roman Period and one of the biggest temple in its time. The Cleopatra Gate and rock-cut Necropolis around it, Roman Bath (known as "Altından Geçme" in Turkish) and Gözlükule Mound, where earlier settlement layers were found are other seen-known archaeological sites suffering from lack of maintenance and challenges for site management. Only one site, Makam Mosque and Roman Bridge is presented with religious rituals because of a tomb known as Daniel's tomb (Hz. Danyal). In addition to seen conserved archaeological remains, there are registered urban conservation zones where traditional and registered buildings that have made minimum destruction to urban archaeological layers and probable archaeologically sensitive areas. In 2013, these areas were registered as Grade III

Anatolian Historic City Centers: Urban Archaeology in Multilayered Context, Fig. 7 Main traces and axes on georeferenced map of Uggeri (1998). (Prepared by the author)

archaeological sites means Museum controlled development. Therefore, the number of archaeological findings is gradually increased. In addition to archaeological findings, unknown-probable archaeological layers that are mostly subsoil resources and archaeological traces like axis, open areas, or topographical foci that will be followed in recent settlement pattern. Main axes (probable Cardo Maximus – Decumanus Maximus) and traces of gridiron pattern could be followed by current pattern of historic city centre and archaeological findings (Fig. 9).

At the junction of Cardo and Decumanus, probable location of Forum is recently used as traditional city centre or bazaar of Tarsus, or civic centre of the settlement that indicates not only a physical multilayered structure but also functional and social continuity through history.

Consequently, Anatolian historic city centers have the potentials of variety and continuity of urban life at the same location. Unfortunately, the most of citizens are not aware of archaeological layers beneath their feet, because archaeological resources – not only subsoil resources, even monumental sites – could not be integrated into urban daily. Therefore, the context of Anatolian historic city centers and multilayered structure is a primary topic of interest for not only archaeologist

Anatolian Historic City Centers: Urban Archaeology in Multilayered Context, Fig. 8 A photograph of bride and groom using sacred water to clean their hands. (Personal archive of the author)

or historians but also professions like city planners, and architects or administrative units like local authorities or conservation councils.

Reading Multilayered Context and Diachronic Documentation

Multilayered context is related with not only physical or morphological continuity and archaeological traces but also socio-economic or socio-spatial urban continuum. There are seen archaeological traces as monumental structures or conserved sites and invisible subsoil urban archaeological potential beneath modern cities. Moreover, urban pattern, streets, axes, or open-spaces could follow physical traces of multilayered settlements. In addition to physical traces, multilayered historic city centers include a socio-spatial continuity defined by land-use, holiness, or rituals. An Anatolian historic city centre would have physical, functional, and economical traces from an Ottoman bazaar that had been settled on a Byzantine market above a Roman forum above an Agora. Similarly, a mosque would has been conserved the holiness of the hill including probably remains of a church, a temple or a sanctuary. Settlement, as a socio-spatial term include tangible and intangible heritage together. Therefore, reading and understanding multilayered context is a complex issue for single disciplines. A methodology to estimate and rank the archaeological potential of different zones of multilayered settlements is needed for proper planning and conservation strategies.

Sommella (1987, 3) defines utilizable documentation of multilayered cities as an interdisciplinary study with the assistance of specialists in the fields of ancient history, archaeology, city planning, topography, history, epigraphy, numismatics, etc. and cooperation between them to achieve a comprehensive understanding of an urban environment by means of horizontal and vertical cross-sectional analyses. Similarly,

Anatolian Historic City Centers: Urban Archaeology in Multilayered Context, Fig. 9 Conserved and estimated archaeological remains in Tarsus (base map indicates contemporary Tarsus). (Prepared by the author)

Cohen (2001, 36–37) indicates needs to broken down city into most basic components to understand in-depth defines. In defined context, diachronic documentation and mapping could be defined as the evaluation of successive occupations of the settlement layer by layer including occupation area, boundaries, gates, main uses, and urban division with vertical and horizontal links. Moreover, monumental and main buildings, traces of urban pattern, and open areas are the elements of diachronic documentation indicating inner layout of cities (Belge 2012, 335).

There are different approaches to manage urban archaeological heritage in multilayered historic city centers. Some of researches have focused on just single period of the settlements. Garmy (1999, 94–96) uses the "urban continuum" to define chronological components of urban archaeological resources instead of just focusing monumental remains or single periods. In defined

Anatolian Historic City Centers: Urban Archaeology in Multilayered Context, Fig. 10 The evaluation of the Real Urban Archaeological Potential in terms of Garmy's (1999) equation (Belge 2012, 332)

context, the formula $Pr = (Pi\text{-}D)^q$ is suggested to determine real urban archaeological potential. In the formula, "Pi" is theoretically the successive occupation of the city and its historical development. "D" means destruction of archaeological heritage by natural or man-made factors "q," the quality of archaeological deposit, is related with topographic factors and archaeological sites' capacity to preserve archaeological deposits (Garmy 1999: 94). The formula is not a mathematical process, instead spatial evaluation of factors let to understand historical development of cities by emerged periods instead of level-by-level (Fig. 10). By means of basic method, real urban archaeological potential in historic city centers will be determined as an outcome of the superimposition of archaeological potential with destruction and the quality of archaeological deposit. Then, urban archaeological potential can be evaluated as urban archaeological character zone according to similar characteristics. While some part of archaeological deposit have been preserved well and some part may be lost its wholeness. Consequently, appropriate conservation strategies and comprehensive planning policies may be developed by referring unique aspects of each character zone, like restricted development, high urban archaeological potential and conservation, controlled, limited development, or reserve areas.

Ancestry Assessment

Richard Wright
Department of Anthropology, University of Sydney, Sydney, NSW, Australia

Introduction

The assessment of ancestry forms part of the suite of analyses undertaken by forensic anthropologists and bioarchaeologists to develop a biological profile. Regardless of the methods used, it is not an easy task to assess a person's biological

ancestry. It is usually not possible to be confident about an assessment unless a person's ancestry lies within one of the four major geographical regions of the Euro-Mediterranean, sub-Saharan Africa, eastern Asia, or Australia/Melanesia. The reason for lack of confidence is that areas between these four regions contain people whose biological properties tend to be blended.

Definition

Ancestry in this context means where a person's ancestors originated before the mass voluntary and forced migrations of peoples that started around the world in the fifteenth century CE.

Key Issues

Why Assess Ancestry?

There are various reasons for wanting to assess ancestry from skeletal remains. These may include answering archaeological questions, such as the identification of persons of African ancestry in Romano British York (Leach et al. 2009). A major question in archaeology is whether the spread of agriculture into Europe was caused by the migration of farming people from Southwest Asia or by the diffusion of cultural practices (Pinhasi and Von Cramon-Taubadel 2009). More remote in time, there are questions such as whether the late Pleistocene Upper Cave skull 110 from Zhoukoudian, in China, is a morphological candidate for being an ancestor of modern people in eastern Asia (Wright 1995).

The process of repatriation raises questions about whether particular skeletal remains are biologically related to the groups to which they are to be repatriated, or whether there has been some confusion of labeling over the decades since they were collected.

In the forensic field, an assessment of an individual's ancestry from analysis of the skeletal remains may help in the search for missing persons. If ancestry has been assessed from skeletal remains, then information about an individual's soft tissue, and the hair color and form, will be more accurate. So assessment of ancestry, when no soft tissue is available, may help in facial reconstruction.

In summary, anthropological evaluation of ancestry offers a quick estimation, which may later be backed up or refuted by analysis of DNA. However, the ability to use DNA cannot be taken for granted. In many non-forensic cases, there are no funds to use DNA to compare results with anthropological assessment of ancestry. There may also be no viable DNA recoverable from archaeological bones. So a need persists for the anthropological analysis of ancestry, using the appearance of the bones themselves.

Assumptions Underlying Assessment of Ancestry

Most assessments of ancestry depend on the skull, because of its high information content available for both observation and measurement. All anthropological methods for determining ancestry are based on the critical assumption that there is systematic geographical patterning of cranial variation (Howells 1989). This assumption of patterning is justified on a worldwide scale (Fig. 1). This scattergram is derived from a metrical analysis of 29 measurements on each of 3163 skulls in the CRANID database (Wright 2008). Though the provenance of each skull is known, the analytical program that produced the chart contained no information about geographical origin. Analysis considered merely likeness and unlikeness, in size and shape, of the skulls. The results are consolidated for plotting as points on the chart, which represents samples in the space of what are known as the first two canonical variates.

If geographical origins are then superimposed onto the purely craniometric chart, it is possible to see that there is a high correlation between cranial form and world geography. The craniometric results produce an approximate map of the world. Therefore, placing an unknown skull on such a map, using its measurements, helps in an assessment of ancestry. An additional working hypothesis is that this patterning is very much due to inherited variation, though there is likely

Ancestry Assessment, Fig. 1 Samples of skulls analyzed by CRANID and plotted in the space of the first two canonical variates following multivariate analysis. No geographical information was available to the program, only cranial measurements. Nevertheless, there is a clear geographical patterning of samples, showing that there is good correlation between geography and cranial form. This correlation is the assumption that underlies methods of assessing ancestry

A

to be some interference from such environmental factors as diet and climate.

How Is Ancestry Assessed?

Early attempts to determine ancestry were hampered by lack of computers. For many decades anthropologists used the two variables of cranial length and breadth, from which they calculated, by hand, the so-called cranial index. Results for this index ranged from dolichocephalic (long headed) to brachycephalic (short headed).

Though much effort was published in this field, the results had fundamental flaws when applied worldwide to an understanding of ancestry. For example, in their cranial index medieval Norwegian skulls are more like Tasmanian Aboriginal skulls than they are like medieval skulls from European Austria – an ancestral implication that is negated by all other indications of ancestry and history.

More durable in their usefulness have been various illustrations of skulls that characterize the properties of skulls from various geographical regions. Use of these illustrations depends on the undoubted ability of the human mind to visually evaluate similarities and dissimilarities between images. Widely used illustrations are those of Rhine (1993). These illustrations have been reproduced elsewhere, and are presented with full annotations in Klepinger (2006). While such illustrations are easy to use by workers with no prior knowledge of worldwide cranial variation, they tend to be limited by being caricatures of geographical extremes. In other words, they do not take account of variation within groups and overlap between groups.

Furthermore, it happens that determination of geographical origin is easiest in the case of adult males, who best manifest the extremes seen in the illustrations. The skulls of females and subadults tend toward the undifferentiated general human form of cranial appearance and, because of much overlap in morphology, their ancestry is more difficult to assess by whatever method is used.

One advantage of such illustrations, compared with the craniometric approach, is that they can readily illustrate such simple but important discriminating properties such as the shape of the anterior margin of the base of the nasal aperture (Fig. 2). Although not a universal panacea for assessing ancestry, this tiny area of the face shows a sharp transverse ridge in people of European and eastern Asian ancestry. This ridge is not seen in people of sub-Saharan African or Australian Aboriginal and Melanesian ancestry where the sill appears smooth.

Multivariate Methods

The development of computers led to multivariate methods of assessing ancestry. Most of these efforts have used measurements of crania, though some have applied multivariate methods to the worldwide distribution of epigenetic traits (Hanihara et al. 2003). An early multivariate aid was supplied by Giles and Elliot (1962). Giles used linear discriminant analysis of eight measurements on American Whites, American Blacks, and Indigenous Americans. To take

Ancestry Assessment, Fig. 2 Two extreme forms of the anterior margin of the base of the nasal aperture. The sharp sill on the left is characteristic of people with European and east Asian ancestry. The smooth form on the right is characteristic of people with sub-Saharan African and Australian/Melanesian ancestry

advantage of this work, the user substitutes measurements from an unknown skull into equations and thereby determines which of the three groups the unknown skull is most alike (Wright 1995).

The method of Giles and colleagues was helpful, but restricted in terms of its worldwide coverage. In 1973, the anthropologist W.W. Howells made available the results of his lifetime study of cranial variation in the human species around the world (Howells 1973). This work was followed up by the general release of the actual measurements on the skulls (Howells 1996). His work is distinguished by a worldwide approach, and the notion of geographical mapping of cranial variation rather than the sterile, and to some provocative, attempt to define the concept of race and races.

The release of Howells's database led to the development of "turnkey" computerized packages for the determination of ancestry, such as Fordisc (Jantz and Ousley 2005) and CRANID (Wright 2008). Both packages use multivariate methods of discriminant analysis. Fordisc has additional forensic samples from America, and CRANID has additional samples from parts of the world not covered by Howells, for example, the Indian subcontinent and Patagonia.

Compared with the simplicity of comparing a skull with illustrations, the multivariate approach means that the user must first get thoroughly competent in taking a series of defined measurements. An advantage of the multivariate approach is that it offers numerical results. These reflect the differing probabilities of an unknown skull coming from particular samples from around the world.

Future Directions

Possible Advances

It seems unlikely that there will be significant advances in multivariate method and theory for use on craniometric data. The algorithms for discriminant analysis were developed in the 1930s. They have advanced little since then, though their use is now widespread with the availability of computer packages. A useful advance, aiming to improve the accuracy of determining ancestry, would undoubtedly come from increasing the worldwide coverage of samples of skulls that can be incorporated into discriminant analysis.

New techniques to take measures have been developed, for example, 3D landmark geometric approaches (Ross et al. 1999) as opposed to measurements by calipers. However, it is difficult to see such methods eclipsing the traditional approaches to worldwide assessment of ancestry, used in Fordisc and CRANID. This doubt exists because there seems little prospect of anybody building up a new worldwide reference collection that matches the comprehensiveness of Fordisc and CRANID. Skeletal collections from many parts of the world are now off limits when it comes to research.

Andah, Bassey Wai

Kola Adekola
Department of Archaeology and Anthropology, University of Ibadan, Ibadan, Nigeria

Basic Biographical Information

An outstanding scholar and teacher, Bassey Wai Andah was born on January 6, 1942. He had his first degree in history at the University College, Ibadan and graduated in 1964. Bassey Andah's keen interest in archaeology was fired by a series of open lectures delivered then by Professor Thurstan Shaw. By that time, he was a final year history student and a member of the audience.

Shortly after graduation, Andah rejected a job offer by the Nigerian Department of Antiquities to take up a postgraduate program at the Institute of Archaeology, London, through a Nigerian Federal Government scholarship. He completed his M. Phil. degree in July 1967 at the institute and thereafter proceeded to the University of California for a Ph.D. under the renowned Professor Desmond Clark.

Bassey Wai Andah gained his Ph.D. in 1973 with his thesis on archaeological reconnaissance in Upper Volta, 1970–1972. He became a faculty member of the Department of Archaeology at the University of Ibadan almost immediately after a successful defense of his work.

In 1978, Bassey Andah was promoted to the rank of a professor at the relatively young age of 36 and was also appointed as head of the Department of Archaeology.

Professor Andah who played a very active role in the formation and stability of the World Archaeological Congress (WAC) became the first African/third president of the world archaeological body having been elected in Delhi, India, in 1994. He had earlier served as the senior representative for the West African region.

Professor Bassey Wai Andah was the president of WAC till his last breath on December 22, 1997. Few months before then, precisely March 1997, he was elected as deputy vice-chancellor (Administration), University of Ibadan.

Major Accomplishments

Professor Bassey Wai Eteyen Andah's distinguished career in African archaeology was hinged on a proper channeling of "expert" curiosity, energy, and experience into the effective analysis of West African cultural patterns. Andah believed that many of the early scholars in West Africa were too uncritical especially in the approaches adopted for the story of man's broad cultural history in the region. Consequently, concepts and mis-concepts coined from other places were utilized wholesale and indiscriminately in the analyses and interpretations of cultural life patterns in West Africa.

Andah's canonical writings reflected in several of his articles published as editor of the *West*

African Journal of Archaeology. Examples of such include Introduction to the Sociology of Settlement History, the Earliest Human Occupation and Settlement in West Africa, and Early Urban Societies and Settlements of the Guinea and Savanna Regions of West Africa – all in the Epistemology of West African Settlements, Special Issue of *West African Journal of Archaeology* volume 25. Others are as follows: The Quaternary of the Guinea Region of West Africa: An Assessment of the Geomorphic Evidence, Iron Age Beginnings in West Africa: Reflections and Suggestions, and The Early Paleolithic in West Africa: The case of Asokrochona Coastal Region of Accra, Ghana – all in the *West African Journal of Archaeology* volume 9.

He promoted the development of cultural resources management which he regarded as a means of linking the past with the present.

Andah carried out extensive fieldwork in various parts of West Africa and lectured in Ghana, the United States, Sweden, and Nigeria.

Professor Andah was prolific as a teacher and a scholar. He wrote over 70 journal articles, authored 4 books, and co-authored 6 books on African archaeology. Having succeeded Professor Thurstan Shaw as the editor of *West African Journal of Archaeology* in 1978, Andah edited the journal till his death on the 22nd of December 1997. He was a teacher of teachers. Professor Andah had little or no patience for non-rigorous archaeological work, always instilling on students that archaeology is neither for the intellectually lazy nor for those without thorough analytical skills. His passion for hard-work and thoroughness showed clearly in the pool of those nurtured academically by him. Many of the current academics in the Department of Archaeology and Anthropology, University of Ibadan, were his students. In fact most of the Archaeology lecturers in other Nigerian universities were also his students, while many of his former students are today archeologists, ethnographers, cultural officers, and museum professionals in different parts of Nigeria.

Bassey Andah was the longest-serving head of the Department of Archaeology and Anthropology, University of Ibadan, having been head from 1978 to 1985 and from 1989 to 1991. It was at his initiative that courses in cultural anthropology were introduced and the first set of graduates in cultural anthropology graduated during the 1986/1987 academic session; the name of the department was changed to reflect the introduction of degree courses in anthropology.

The first Nigerian professor of archaeology laid the foundation for the active participations of Nigerians in the activities of the World Archaeological Congress. Today, Nigeria has an enviable record of service in the global body, while the country has the highest number of WAC members in the West African region.

During his lifetime, Professor Andah received a plethora of academic awards including the Fulbright Senior Scholars Fellowship Award in 1984 and the CODESRIA/Rockefeller Senior Scholars Fellowship Award in 1991/1992. In 1993, he received the Distinguished Historian Award for APEX Museum, Atlanta, Georgia, USA, and secured the Australian University's Merit Award in 1995.

In recognition of his academic brilliance and numerous contributions to African archaeology, a memorial lecture was instituted in his honor, while the library of the Department of Archaeology and Anthropology, University of Ibadan, was named after him.

Andarayan: Agriculture

Philip J. Piper
School of Archaeology and Anthropology, Australian National University, Canberra, ACT, Australia

Introduction

The archaeological site of Andarayan is located close to the Cagayan River, in the Cagayan Valley, just east of the modern town of Solana, northern Luzon, Philippines. Richard Shutler Jr. conducted limited test excavations at the site in 1978 (Snow et al. 1986). Within the alluvial deposits, Shutler recovered a large assemblage of red-slipped pottery, clay earrings and spindle whorls, and fragments of ground stone tools. Some of the pottery had been produced using an organic temper of rice chaff and broken stem segments to aid in the bonding of the clay during firing. The general shape of the glume imprints identified in the pottery indicated that the impressions were from rice *Oryza* and intermediate between the common cultigen *O. sativa* and its wild progenitors. A single AMS date of 3400 ± 125 years BP or 4000–3350 cal. BP (no code) confirmed that the pottery was produced during the early–mid second millennium BCE. From this evidence Snow et al. (1986) argued that this represented the earliest evidence for the cultivation of rice in the Philippines and across most of Island Southeast Asia (The earliest known rice temper in Island Southeast Asia is from the cave site of Gua Sireh, Sarawak, Malaysian Borneo, and is dated to c. 4,200 years ago. Rice has also been identified to the north of the Philippines at late Dabenkeng sites such as Nanguanli in Taiwan dated to c. 4,700–4,200 years ago).

Key Issues

Andarayan is by no means a unique archaeological site for northern Luzon but rather one of many such sites found within the Cagayan River Valley that have produced a similar suite of material culture. These include Magapit, Nagsabaran, Conciso, and Irigayan, and there are sites of a similar date to the north in the Batanes Islands (Mijares 2007). But the lower Cagayan Valley sites are unique in that many of them are very large shell middens, dating from Neolithic and Iron Age times and possibly even pre-Neolithic as well (more research is needed on chronology). The earliest occurrence of many of these Neolithic artifact types and technologies in the Philippines, like pottery and ground stone tools, is at these sites in the Cagayan Valley. Many such artifacts have strong similarities to the types of material culture identified in Taiwanese Neolithic sites dating to a similar period. For example, the red-slipped pottery found in southeastern Taiwan and northeastern Luzon has great affinities in form, surface finish, and decoration. The spindle whorls are very similar in morphology to those found at sites such as Fengpitou in southwestern Taiwan.

Although it has been argued that these Neolithic peoples were sedentary agriculturalists who brought rice agriculture with them, the evidence for intensive cultivation has yet to be identified, and Andarayan remains the only site of this date to have produced any evidence for the presence of

rice in the region (Andarayan is unusual in that it is the only site in the Cagayan Valley to have produced red-slipped pottery with an organic temper. The pottery from all other sites in the region has either fine- or coarse-grained inorganic tempers). There is, however, evidence to suggest that, along with new types of material culture, domestic pigs were introduced to the Philippines by c. 4,000 cal. BP.

Collectively, Andarayan and these Cagayan River Valley sites are considered to reflect one of the earliest arrivals of the Austronesian-speaking peoples from Taiwan into Luzon around 4,000 years ago. The settlement of the northern Philippines from Taiwan represented the initial step in a process of migration and colonization by the Austronesian-speaking populations that would eventually encompass two thirds of the globe from Madagascar in the west to New Zealand and Easter Island in the east and is considered the most extensive movement of human populations recorded in prehistory (Bellwood 1997).

Andean Petroglyphs

Andrés Troncoso
Departamento de Antropología,
Universidad de Chile, Santiago, Chile

Introduction

The archaeology of the Andes is recognized worldwide for the complexity of the sociohistorical developments that have occurred in the region and for the wealth and monumental nature of its archaeological record. This has led researchers to pay great attention to study of the great architectural complexes of the Andes and to a series of elements of material culture which can be catalogued as art, such as ceramics and metalworking. Although petroglyphs are a recurrent material record in the Andes, they have not been studied in the same depth as other material evidence from the pre-Hispanic era. An overview of Andean petroglyphs is realized in this entry.

Definition

Petroglyphs are a particular type of rock art, characterized by the production of images on rock supports through extraction of the surface material of the rock by engraving, scraping, and/or incision. These extractions create lines or areas to depict specific images which make up the motifs of Andean petroglyphs. In some cases, the lines or the areas between them may be filled with paint. Petroglyphs are part of a broader corpus of Andean rock art which also includes paintings, geoglyphs, and carved outcrops.

Description

The practice of creating petroglyphs was recurrent in the different regions of the Andes and throughout a large part of their historical sequence. This wide spatial and temporal distribution implies great heterogeneity in the visual representations.

In spatial terms, although petroglyphs are found on the different altitude floors of the Andes, their presence diminishes notably in coastal spaces. In temporal terms, although further studies are still needed to define the chronology of these manifestations in various regions, their production can be clearly recognized since at least 6000 years ago (Berenguer 2000; Guffroy 1999; Tumi 2011). Nevertheless, it may be noted that in some sectors such as northwestern Argentina, the presence of rock art in the form of paintings goes back to the start of the Early Holocene. Manufacture of petroglyphs continued in different sectors of the region after colonization by the Spanish, but at a lower intensity than in earlier moments, consistent with the inquisitorial practices of the crown (Hernández Llosas 2006; Hostnig 2007; Martínez 2009).

Despite the spatial, temporal, and visual variety of Andean petroglyphs, some very general characterizations can be proposed about their iconography to introduce the reader to the visual richness of these manifestations. The most recurrent motifs in Andean petroglyphs are nonfigurative (Fig. 1). They may be simple geometric units like circles, squares, or lines, represented either in isolation or containing interior elements such as other geometrical figures (e.g., concentric circles, inscribed squares, squares with internal lines) or else combined with other geometric units to form motifs like agglutinated circles, circles connected by lines, interwoven inscribed squares, etc. Some of these nonfigurative representations are similar between the different spaces of the Andean region, but it is not known whether this is a result of shared visual codes or of convergences within independent iconographic processes. Indeed, some of these motifs are shared with other regions of the planet due to their simplicity, or to the finite character of the geometric units of which they are composed.

Figurative motifs are varied across the region, although some common trends may be observed. There is a rich corpus of zoomorphic representations, reflecting part of the local ecologies, but also animals which were important for local imaginaries and practices. A symptom of this is the scarce representation of marine fauna, consistent with the low frequency of petroglyphs in coastal spaces. One exception is the Las Lizas style from northern Chile, which depicts sharks, dolphins, tuna fish, etc. (Niemeyer 1985). In contrast, Andean camelids (Llamas, Alpacas, Guanacos, and Vicuñas) are perhaps the most popular animals in the repertoire of Andean petroglyphs. They may be represented in isolation, in herds, or in scenes where they interact with humans (Fig. 2). The latter include hunting, rodeos, herding/grazing, and caravan transport (Berenguer 2000; Guffroy 1999). Their recurrence is consistent with the high economic, social, and symbolic value of camelids in the Andes.

Andean Petroglyphs, Fig. 1 Petroglyph with nonfigurative motifs, anthropomorphs, and camelids, northern Chile. (Photo courtesy of Mauricio Uribe & Flora Vilches)

Human figures are also recurrent in the various spaces and times, with no clear trends observed in their distribution. Despite their great heterogeneity, the predominant representation seems to be of simple anthropomorphs with lines for the body and a circle for the head. In other cases the bodies may have volume, either square or circular, and in some the trunk is decorated as if with clothing. Considering the high symbolic and identity value of textiles in the Andes, some works have examined these representations of clothing to identify the affiliation of the anthropomorphs carved in rocks (Lopez Campeny and Martel 2014). A similar situation appears to occur with headdresses, which are recurrent in the region and are related with aspects of identity of the pre-Hispanic Andean populations.

Andean Petroglyphs, Fig. 4 Human head with headdress, central northern Chile

Andean Petroglyphs, Fig. 5 Therianthropic figure of the Aguada culture, northwestern Argentina. (Photo courtesy Norma Ratto)

Heads in particular are a recurrent motif (Fig. 3). They may be naturalistic representations or transformed following at least two basic principles: *schematizations*, which include a series of nonfigurative elements in the face, "distorting" its naturalness, and *combinations* which integrate human and animal elements in the composition of the face, especially attributes of felines such as spots or teeth. Some of them may also include headdresses (Fig. 4). Although the spatial distribution of the different facial expressions of the heads has not been much studied, the fact remains that they are a body part which was highly valued in the Andean world, being associated with notions like ancestors, fertility, and power. The best-known cases to date suggest that heads are distributed from formative to state contexts; however, they appear not to be continued after contact with the Spanish Empire, possibly due to the importance of this motif in the imaginaries of the indigenous populations.

The combination of multiple beings in a single representation is not very frequent in Andean petroglyphs; however, therianthropy is found, as noted above, when human and feline attributes are combined. In some cases it has been postulated that human-camelid combinations are represented. By the same token, combinations between animals are even scarcer; one well-known case is that of the Aguada petroglyphs in northwestern Argentina, where snakes are combined with felines, and even human elements may be included (Fig. 5).

Andean Petroglyphs, Fig. 6 Scene with mounted figure in a petroglyph of the colonial period, northwestern Argentina. (Photo courtesy of Mercedes Podestá)

Andean Petroglyphs, Fig. 7 Petroglyphs known as cattle marks (nineteenth–twentieth centuries) associated with creole communities, central western Argentina. (Photography from the files of the National Institute of Latin American Anthropology and Thought – Argentina)

The known iconographic corpus of petroglyphs post-contact with the Spanish Empire is less varied than the pre-Hispanic and may be divided into two large groups. One set consists of the petroglyphs associated with the colonial era (sixteenth to early nineteenth centuries), which have been studied intensely in recent decades. In general, they present similar themes in the different regions of the Andes with representations of Christian crosses, scenes of people mounted on horseback, churches, and priests (Fig. 6). Nonfigurative representations like chessboards have also been recognized, as well as writing with indications of calendar dates (Hostnig 2007; Martínez 2009; Strecker 2016).

The other set are petroglyphs created in the nineteenth to twentieth centuries, associated with creole communities rather than necessarily indigenous populations. They have been little studied and consist mainly of inscriptions with dates, names, and nonfigurative motifs like circles or lines. In central western Argentina and central northern Chile, these representations are known as "cattle marks" and were supposedly made by cattle herders who took their cattle across the Andes; the marks would have served to delineate territorial borders and for communication (Podestá et al. 2011) (Fig. 7).

Further to this brief characterization of the iconography of Andean petroglyphs, we do not presently know of any spatial or temporal trends in the distribution of the motifs adopted. Although petroglyphs created by hunter-gatherer groups have been recognized, they were created for the most part by agricultural and state societies.

Historical Background

The historical development of research into Andean petroglyphs varies among the different countries and sectors of the region. Although in general an early interest in this material record is observed among the first scholars to study the Andes, the intensity, depth, and orientation of investigation over the course of time have generated different research traditions in different countries. For example, in Argentina and Chile, we find a great accumulation of investigations and works oriented toward the problems raised by petroglyphs among the multiple social, political, and economic dynamics of pre-Hispanic communities. In recent years, especially in Argentina, collaborative investigations with communities have become very frequent. In Bolivia on the other hand, thanks to the work of the Bolivian Rock Art Research Society (SIARB), a tremendous effort has been made in recent decades to record, catalogue, conserve, and appreciate the country's rock art, together with an emphasis on regional studies and the characterization of colonial rock art. A similar

orientation can be seen in Colombia, thanks to the actions of a series of bodies, among them the Rock Art Research Investigation Group (GIPRI), with great emphasis on conservation, cataloguing, and appreciation of the petroglyphs. In Peru, studies on rock art have intensified over the last decade, oriented more toward systematizing the sets of petroglyphs, with discussion of their chronology and relation with the landscape.

These examples of the different paths followed by research reflect how complex it is to take a historical approach to the study of Andean petroglyphs, since at bottom it is a story of highly fragmented investigation in the different sectors of the Andes, and has not yet been defined by common research topics. Nevertheless, some general points can be noted.

First, despite the rich documentary corpus left by the conquest and the imposition of Spanish power in the region, there are few documentary sources which refer to petroglyphs and rock art. Martínez (2009) suggests that this may be due to multiple factors, one of which is that Europeans may have seen the petroglyphs as indecipherable texts from the past.

Second, although some descriptions exist, recorded by travelers and military personnel as early as the eighteenth century, no tradition of investigation was formed until late in the nineteenth century and early in the twentieth century, after the creation of the Andean states on their independence from Spain. In general, these studies were mainly descriptive, and on occasions focused on deciphering the meanings of the representations in terms of ritual practices, mythologies, or even maps. Of course, these first approaches formed the basis on which the researchers of the mid-twentieth century would work, continuing to address areas like classification and systematization into sets and chronology and combining rock art information with that of other archaeological contexts. Important figures in this story are Juan Bautista Ambrosetti and Eric Boman (Argentina), Jorge Iribarren and Hans Niemeyer (Chile), Eloy Linares Málaga (Peru), José Pérez Barradas and Miguel Triana (Colombia), among others.

Third, researchers have tried to incorporate understanding of Andean petroglyphs into the archaeological problems of the region. To do this, theoretical-conceptual and methodological frameworks have been drawn up which in some degree dialogue with general changes in worldwide theoretical frameworks, and those particular to the Andes, without however being remitted and reduced to the simple opposition between processual and post-processual archaeology. Nevertheless, it also occurs that these cases coexist with approaches which were more descriptivist or based on aesthetic or art history perspectives. These variations are associated with the particularities and tradition of research in the different Andean countries.

Fourth, despite the scarce documentary evidence associated with the production of petroglyphs, rock art information has been combined with archaeological, ethnographic, and ethnohistorical data in different parts of the Andes to attempt interpretations of the symbolic, mythological, and landscape aspects related with Andean petroglyphs. This research tradition is proper to the Andes, and contains history going back to before the proposals of post-processual Anglo-Saxon archaeology.

Fifth, today we are witnessing huge growth in investigation into rock art, and petroglyphs in particular, in the Andes. This is shown by the large number of publications on this subject (e.g., Boletín SIARB and Rupestreweb), the organization of national and Latin American conferences, the emergence of multiple theoretical-methodological discussions, and regional studies, all of which position the Andes as a vibrant space in world rock art archaeology. These processes are accompanied by important collaborative work with local communities, as well as cataloguing, recording, and appreciation of this delicate cultural heritage.

Key Issues/Current Debates

As in many parts of the world, one of the key issues in the study of Andean petroglyphs is determining their chronology and cultural

affiliations. Although progress has been made over recent decades, identifying zones with clear, well-established historical sequences of petroglyph production, further studies in this field are required in other spaces. This interest in defining visual sets with historical value has been accompanied by theoretical-methodological discussion on what constitutes a style, how styles are defined and their implications in terms of identity or information flows.

One aspect that is widely discussed in the Andes is the relation between petroglyphs and landscape. Although a number of approaches exist, they can be grouped around three basic perspectives: (i) the relation between petroglyphs and mobility, in that they serve to mark both routes and territorialities; (ii) the relation between petroglyphs and landscape construction in terms of endowing a specific space with meaning by carving rocks; and (iii) the ways in which these petroglyphs create historically constituted memory and experiences. These approaches have combined the information obtained from rock art with data collected from other archaeological material records, as well as Andean ethnohistory and ethnography (Castro and Gallardo 1995–96; Martel et al. 2012). However we know of no specific studies investigating or comparing the forms of landscape construction implemented by petroglyphs in relation with other forms of rock art such as paintings or geoglyphs, although a landscape archaeology approach is common to investigations into the different rock art manifestations in the Andes. As may be expected, many of these studies are based on intensive regional orientation programs (e.g., Strecker 2016).

One aspect which is only now being discussed in some parts of the region refers to the technological dynamics of petroglyphs. Theoretical-methodological proposals have been offered which take up notions of the anthropology of technology and/or craft production, with a strong emphasis on replicative studies. These proposals have given rise to attempts to understand not only the instruments used in creating petroglyphs, but also the operative chains associated with their production, the investment of time, and energy as they relate to intervention in these spaces, the types of design, and the social dynamics of production (Alvarez and Fiore 1995; Valenzuela 2007; Vergara and Troncoso 2015; Vergara et al. 2016).

Such technological and spatial studies coexist with other, more iconographic approaches focused on study of the visual nature of petroglyphs in order to discuss many aspects of social life, such as social differentiation, dynamics of identity and territory, and the domestication of camelids; the latter is a key moment in the pre-Hispanic history of the Andean peoples (Aschero 2000; Bray 2002; Guffroy 1999; Gallardo and Yacobaccio 2005). Through these multiple perspectives, the study of Andean petroglyphs has become integrated with archaeological studies of the pre-Hispanic period in order to understand past sociohistorical processes in the Andes and the role played by this type of rock art in these dynamics.

Recognition of petroglyphs specific to the Inca state, or Tawantinsuyu, has opened up a series of debates in the last decade. A group of works has focused on recognizing the presence of this material expression in different spaces of the Tawantinsuyu, especially its southern provinces. These approaches have discussed the authorship of these representations and whether they are a product of the incorporation of Inca visual elements by local populations or were manufactured by agents of the state; in the latter case, they would be part of the material resources deployed by the state in its annexation processes in the region. There are interesting theoretical aspects to this discussion, as it establishes an analytical separation between the manufacture of petroglyphs and the circulation of motifs on rock supports.

Although the presence of rock paintings attributable to the state is recognized in the Inca heartland, the situation is not conclusive for petroglyphs. However it is known that state agents of the Tawantinsuyu sculpted rocks with geometric forms and zoomorphs in Cusco and its surroundings (Joyce 2015). This group contains the so-called models which represent fields of crops with canals; these have been recognized

Andean Petroglyphs, Fig. 8 Inca models from northern Chile. (Photo courtesy of Mariela Pino)

both in the Inca heartland and in provincial sites (Berenguer 2000; Meddens 2006). As these models tend to be sculptures and engravings, they have not traditionally been considered as petroglyphs, since their production implies a different way of working stone (Fig. 8).

Finally, the recognition and systematization of a set of petroglyphs from the colonial and republican periods has been a vibrant and important line of investigation in Andean archaeology. It has served to evaluate on the one hand the common elements associated with the discourses and imaginaries of the indigenous communities with respect to the Spanish conquest; and on the other the expressive possibilities and limitations imposed by the Spanish Empire on the traditional practices of indigenous communities. Some lines of work compare colonial petroglyphs with other contemporary media in order to discuss the different freedoms, expressivities, and values which could be deployed on different material supports under Spanish domination.

International Perspectives

In general terms, Andean petroglyphs are little known and discussed globally. The same is true of the rock art of the Andes, with the exception of the Nasca geoglyphs. Nevertheless, study of these petroglyphs has gradually become internationalized through the organization of local rock art federations associated with IFRAO and the organization of international conferences, in particular the two IFRAO Conferences held in Bolivia and Brazil. Regional researchers are publishing their works in the principal world journals with increasing frequency, thus publicizing the study of Andean petroglyphs and incorporating it into world archaeology.

As we shall see in the following section, we believe that there are at least two lines of work which are proper to the Andes and can contribute to world rock art archaeology. On the one hand, the existence of different types of societies which manufactured petroglyphs (from hunter-gatherers to states) makes the Andes a suitable space for comparative and intercultural studies and theoretical orientation about petroglyphs. On the other, the rich corpus of ethnographic knowledge about technology and creation processes also contributes to technological and interpretative study of these petroglyphs, but from an Andean ontology; this proposes other points of view that differ from the most frequently cited cases in global rock art archaeology, which refer to Australia and South Africa.

Future Directions

There is no doubt that the study of petroglyphs in the Andes has been a fertile and popular field in recent decades. However a series of tasks and subjects for further work can be glimpsed for the future. As we have indicated, although in some regions of the Andes, good systematization work and chronological definitions have been carried out for petroglyphs, this is not the case throughout the whole region. In many places work is needed to continue with the systematization of the sets of petroglyphs and to refine the chronologies using a combination of lines of evidence which together can give them solidity. It is quite feasible to achieve this object in the short to medium term given the great intensity of systematic and theoretically oriented investigations on Andean petroglyphs. Exploring ways of dating petroglyphs directly is a task which must be undertaken jointly with the efforts being made worldwide.

In addition, there is a series of other important aspects that need to be addressed. One subject that has been little explored is to determine whether something exists that we can describe as "Andean" rock art or petroglyphs. In other words, interregional, diachronic comparative studies are needed to try to recognize codes and patterns reflecting similar principles which would allow us to define a set of basic elements recognizable as those of Andean petroglyphs. These principles must be thought of not only in iconographic terms but also in terms of the composition of sets and landscapes, and articulation with pre-Hispanic social life. If an entity can be recognized which is definable as "Andean petroglyphs," we must try to understand when it came into being, under what conditions, and its temporal and spatial extent. This evaluation appears important not only because it implies comparative views and collaborative work between researchers from different countries but also because traditions of rock art production covering wide temporal and spatial ranges have been recognized in other regions like South Africa and North America.

There is a line of work that can be carried out in the Andes region which is impossible in other regions; it should therefore be a priority in our local agenda. We refer to comparative study of Andean petroglyphs in relation with the different sociocultural formations particular to the region. The petroglyphs of the Andes were produced by groups with different degrees of social complexity, ranging from hunter-gatherers to state societies; moreover, the latter included different types of states (e.g., Chavin and Inca). This privileged situation allows comparative and intercultural exploration as to whether trends exist in the sociopolitical, economic, and productive aspects of petroglyph production in relation with the level of social complexity or the politico-economic nature of the human groups that manufactured them. From an archaeology of colonialism, the presence of petroglyphs from both the Inca and Spanish periods allows us to discuss the articulations between the materiality and practice of rock art and the colonialist dynamics deployed by two states founded on very different imperial expansionist ontologies and practices. This type of perspective on Andean petroglyphs would certainly be an important contribution to world rock art archaeology, and would position the Andes as an important space for this discipline, both for its research potential and for the richness of the petroglyph record.

Although in South American archaeology in general, and Andean archaeology in particular, the technological aspects of petroglyphs have been studied with a fair degree of intensity in recent years, deeper approaches are needed to go beyond identification of the instruments used and the formal delineation of the operative chain. We believe, therefore, that we can recognize two possible paths to follow. On the one hand, we need to go more deeply into the study and comprehension of Andean petroglyphs from the logic of the economic and political aspects of craft production. This approach will enable us to continue to integrate petroglyphs into discussions established on the pre-Hispanic production dynamics of a series of other material records, assessing how the different media are inserted and articulated in the sociopolitical processes of the past.

On the other, although the ethnohistorical record contains scarce references to the production of petroglyphs in the past, anthropological works have addressed what we might call an Andean understanding of the technology (Allen 2015; Van Kessel and Condori 1992). Starting from a study of ethnohistorical records and current ethnography, it has been recognized that the technology of the Andes is imbued with a series of active ontological relationships with nonhuman others, as well as with values and symbols which differ drastically from those of the Western world. These relations and principles not only define operative chains specific to the objects but also endow the act of production with a social density, and the objects produced with capacities of animation, which make them unique in the world. Petroglyph production may not have been exempt from these particularities, although there are no

particular studies which address this aspect. Future works are needed to follow this line, not only in search of a more spatially and historically located understanding of Andean petroglyphs but also as a contribution to world rock art archaeology by suggesting models and interpretative proposals arising from different ontological horizons. These can be discussed and compared with those recognized in other parts of the world to try to understand the human phenomenon of petroglyph production.

Last but not least, the whole rich corpus of Andean petroglyphs forms part of the social landscape in which today's local communities live their social lives, some aspects of which maintain a set of practical, discursive, and symbolic relations with this material record. This in turn leads to two lines of work which are relevant to archaeology. First, collaborative work oriented toward recovering the knowledge and practices of local communities in relation to petroglyphs. This process does not necessarily seek to essentialize indigenous knowledge into something ahistorical in order to use it as a pathway to interpretation. Rather it allows us to understand how today's communities weave a series of relations with materialities of the past; how these are integrated into today's landscapes by these groups, and so to discuss the values and meanings of the petroglyphs for those groups who live in the region today. A critical historical view of this process also allows us to deploy these interpretations as narratives through which to understand the pre-Hispanic past.

Second, to accompany and collaborate in the processes deployed by these communities for the recovery, recognition, and appreciation of their traditional knowledge, practices, and landscapes. Above any economic value, we believe that the central element of this process is to restore the dignity of the local communities and to recover and recognize the value of other viewpoints and discourses on a practice and a material record which by its visual nature invites interpretation. It may be noted that this process has already begun in several parts of the Andes, and will probably intensify in future years.

Andernach-Martinsberg (Magdalenian): Geography and Culture

Martin Street
Monrepos Archaeological Research Centre,
Museum for the Evolution of Hominin Behaviour
Schloss Monrepos, Neuwied, Germany

Introduction

Andernach-Martinsberg is, together with the site of Gönnersdorf, one of two major Magdalenian settlements in the German Central Rhineland. Burial under Late Glacial ash deposits of the Laacher See volcano protected the site from destruction, making possible detailed insights into many aspects of human life during the Magdalenian. A broad range of analyses informs on technology and subsistence strategies, spatial organization of living space, mobility of people in the landscape, and sociocultural behavior represented by ornament and artistic expression.

Definition

Much knowledge of certain periods of the Paleolithic is defined by a few exceptional sites, which for reasons of function or duration of occupation, but crucially also due to favorable conditions for their survival, preserve a range of information rarely available in the case of most archaeological sites of this age. In the case of the late Paleolithic, Andernach-Martinsberg is such a rare site.

Key Issues/Current Debates/Future Directions/Examples

Research History

The Andernach Paleolithic site lies on the Martinsberg, a middle Pleistocene lava flow which forms a slope extending toward but not reaching the River Rhine, a few hundred meters to the north. The site is secure from flooding and sheltered by the local topography and close to where the river flows northwestwards from the low-lying Neuwied Basin into the narrow channel of the Rhine Gorge. The comparable Magdalenian site of Gönnersdorf lies only 2 km away, to the north of the Rhine in view of the Martinsberg.

The Martinsberg site was originally discovered in 1883 and excavated and subsequently published by Hermann Schaaffhausen (1888). The anatomist and antiquary from Bonn, an advocate for the presence of "Diluvial Man" in the Rhineland, saw the site as a vindication of his views.

A reanalysis of the 1883 Andernach lithic and faunal assemblages was carried out following the discovery of the neighboring Gönnersdorf Magdalenian site in 1968 (Bosinski and Hahn 1972). The location of the Martinsberg site was then rediscovered during earthmoving in 1978. Excavations between 1979 and 1983 (Veil 1982; Street 1995) and from 1992 to 1994 (Holzkämper 2006) showed the presence not just of the expected Magdalenian horizon but also a younger late Paleolithic horizon assigned to the "Federmessergruppen" (Penknife Point groups).

The excavations from 1979 to 1983 investigated something over 100 m^2, uncovering three distinct concentrations of Magdalenian lithic and faunal material (C 1, C 2, and C 3). The investigation of a similar area from 1994 to 1996 discovered a fourth Magdalenian concentration (C 4) 15 m to the south.

Chronology and Environment

The age of the Magdalenian settlement of the Martinsberg is known quite accurately due to series of radiocarbon dates on the bones of hunted animals, which fall around 13,000 BP, equating to approximately 13,800 calibrated years BCE. This was near the end of a cold and very dry climatic event and some 1,000 years before the onset of the Late Glacial Greenland interstadial (Street et al. 2006). The species hunted during the Magdalenian occupation at Andernach are typical for steppe-tundra conditions – horse, reindeer, arctic fox, and varying hare – whereas woodland species are absent.

Settlement Features

That concentrations C 1 and C 3 had been dug into by the 1883 excavation is shown by conjoined lithic material recovered a century apart, and C 1 is also truncated by the foundations of a house built later. C 4 was also truncated by recent disturbances. After the deposition of the Magdalenian archaeological horizon, some areas of C 2 and C 3 were heavily disturbed by erosion into fissures in the underlying basalt. This clearly took place before burial by Laacher See volcanic ash. Before this happened some material from both the Magdalenian and Federmessergruppen phases was vertically displaced and mixed by frost heaving and/or bioturbation.

Features C 1, C 3, and C 4 are characterized by areas of denser (C 1, C 3) to diffuse (C 4) paving formed of sometimes very large slabs of slate, quartzite, and other types of rock, sometimes stained by red ochre and by concentrations of lithic artifacts, faunal remains, and other items. The concentrations are associated with complexes of pits and are interpreted as stable, enclosed dwelling structures. They clearly represent complex and dynamic settlement activities over an appreciable length of time, perhaps during repeated occupations over several years.

C 2 is defined by a discrete scatter of blanks, tools, and waste of flint and numerous ivory fragments around and within a natural fissure open to a depth of perhaps 2 m at the time of the settlement. The surrounding material was subsequently eroded into the fissure, truncating the higher-lying archaeological horizon and redepositing finds at various depths. Shallow patches of red ochre-stained sediment on the truncated surface suggest that any pits originally present were largely destroyed. Patches of red stained sediment in the fissure fill may represent the fills of these pits or merely sediment blocks transported by erosion. Activities at C 2 included the production and repeated sharpening of flint burins and probably the working of ivory. Refitted artifacts show a connection to C 4, and it is possible that C 2 was a specialized satellite activity area linked to the dwelling structure.

Indications for the use of fire are limited to traces of thermal reddening of slabs and cobbles of schist and quartzite and quantities of fire-cracked quartz cobbles (pot boilers). Bones from the Magdalenian horizon show almost no traces of burning and very few burnt lithic artifacts are present. Rocks with concave surfaces (geodes, conglomerate) are found and would have been suitable for use as lamps fueled with animal fat, which may have provided light and some heat within the dwelling structures. However, since the many fire-reddened slabs and fire-cracked cobbles suggest that fires were lit in contact with the paved surface, it is possible that contents of hearths (ash, charcoal, and burnt objects) were methodically cleared away and possibly dumped outside the excavated area.

Artifacts

Analyses of the lithic artifact assemblage (Floss and Terberger 2002; Holzkämper 2006) include studies of raw materials, technology and typology, conjoining and plotting knapping sequences, and examination of assemblage variability. Samples were also studied for trace wear.

It is difficult to quantify the lithic material from the 1883 excavation, now divided between a number of museums, but almost 1,000 finds can still be located and seem to be representative of the better analyzed samples from the more recent excavations. Between them, C 1–C 3 produced more than 23,000 Magdalenian artifacts of which >5,300 were larger cores, flakes, blades, or bladelets. The most recently recovered Magdalenian assemblage (C 4) yielded almost 20,000 artifacts, over 600 of which were blades and bladelets.

Artifacts recovered from C 1 and C 3 are predominantly made of limnic quartzite and show a balanced mix of tool forms typical of the Magdalenian. C 2 is characterized by the manufacture and re-sharpening of burins associated with waste from ivory working. In C 4 the importance of activities involving burins is shown by 129 of these forms, almost 50% of the tool inventory, and more than 700 recovered burin spalls.

A wide range of non-cryptocrystalline rocks brought to the site were modified as artifacts in several ways (Eickhoff 1995). Various types of

pebbles obtained from river gravels, some of them quite standardized, were used as hammer stones or retouchers for the manufacture of lithic artifacts, while larger cobbles were probably used for processing a range of other inorganic or organic materials.

Many of the rocks used as constructional material show complex patterns of modification, such as splitting and notching of the edges of blocks and slabs. Some of the notches may have been created to accommodate perishable wooden posts or stakes.

Numerous artifacts of bone, reindeer antler, and mammoth ivory typical for the later Magdalenian include eyed needles of bone, spalls and projectile points of antler and ivory, antler batons percés, and baguettes demi-rondes (Tinnes 1994). Waste debitage shows the manufacture of such items at the site.

Subsistence

The fauna comprises mainly larger and smaller mammal species, with some evidence for birds and fishes (Poplin 1972; Street 1993). In terms of food value, the most important species is the horse. Together C 1, C 2, and C 3 yielded the remains of at least 12 horses, and at least three individuals are present in C 4. Analysis of the age patterning of the animals killed suggests prey selection, with Magdalenian hunters targeting family groups of mares and young animals. Since almost all parts of the horse skeleton are present, albeit in varying proportions, at least some kill sites must have been close enough to the Martinsberg to enable utilization of entire horse carcasses, probably after dismembering into transportable portions. Standardized butchering processes, such as disarticulation and filleting of the carcass, are revealed by regular patterns of cut marks on bones. Intensive fracturing of bones for the extraction of marrow and grease is also well documented.

Other species play a far less significant role in the diet. Reindeer is represented in C 1, C 2, and C 3 by no more than three individuals interpreted as food remains and is also present in C 4 where it was not possible to calculate the number of individuals. By contrast, antler is very common in the form of modified tools or waste from their manufacture and in some cases demonstrably comes from collected shed antlers.

Of the smaller taxa, arctic fox is mainly found in the large paved structure C 1, with appreciably less material from C 2 and C 3. At least five or seven individuals are represented, calculated on the postcranial skeleton and dentition, respectively. Only a single tooth fragment was recovered from a pit in C 4. Only 24 specimens from the 1979–1983 excavation are identified as varying hare, most of them from C 2, with at least two individuals represented. Several vertebrae from a pit in C 4 probably deposited in articulation may underline the connection between this area and C 2.

Bird species found in C 1 and C 3 include ptarmigan (single bones), swan, and goose. The avifauna from C 2 comprises only ptarmigan and raven, each represented by at least two individuals. Bird wing and foot bones may primarily derive from use of ornamental feathers and claws and not represent food remains. The few fish remains recovered from the paved structures C 1 and C 3 include salmon or sea trout, while C 2 has these species and a single find identified as grayling.

Mammoth is represented only by ivory. C 1 contained three female figurines, some ivory projectile points, and a unique core on a tusk segment, and the small area of C 3 also produced some ivory. C 2 has been mentioned as an area perhaps specialized in ivory working and several figurines were recovered here, while a single female figurine and three ivory fragments are all that was found in C 4.

Season and Duration of Occupation

Seasonal information from the analysis of faunal remains suggests that Andernach was occupied over an extended period of the year.

Tooth eruption data for horse and reindeer suggest an autumn/winter occupation for Andernach C 1 and C 3, and the importance of arctic fox in C 1 can perhaps be interpreted as an indication of winter trapping of animals for pelts (which might also apply to varying hare). The presence of migratory birds (geese and swan) could equally

suggest autumn/winter occupation if these species had similar patterns of migration to that of today.

Vertebrae of large adult salmonids (up to 1-m length and more) at Andernach clearly represent anadromous fish and could be from individuals caught in spring/summer when ascending the river to spawn. The majority of specimens are from C 2, but two vertebrae of a very large salmonid were found in a pit of C 1 which also contains horse teeth of a young horse killed in autumn. It is therefore probable that site history is complex, with settlement probably extending over longer periods of time and at different and/or overlapping seasons.

Mobility and Social Networks?

A range of exogenous lithic raw materials were imported to the Central Rhineland by Magdalenian people (Floss 1994). They are seen as proxies for the mobility of groups within the landscape, providing information on their movements over middle- and long-range distances and contacts to other regions. Several varieties of fine-grained Tertiary limnic quartzite available at distances of up to 30 km are generally of very high quality and suitable for the production of large blade blanks.

Lithic resources located much further (>90 km) from the Central Rhineland include high-quality Cretaceous flint from primary outcrops in chalk formations some 120–130 km to the northwest, in the region of the German-Dutch-Belgian border, which possibly indicates contact or identity with Magdalenian groups at the northern edge of the loess belt. Cretaceous flint was also collected from glacial moraines some 100 km north and northeast of the Central Rhineland. A small number of artifacts made of chalcedony were probably obtained from the lower Main Valley some 80–100 km to the southeast.

The exact relationship between the different regions represented by these raw materials of disparate origin is unknown. Possibly distinct Magdalenian groups exploiting the different regions met at Andernach, which would then have the character of an "aggregation camp." Alternatively, a single larger group occupying the Central Rhineland for much of the year may have dispersed into the different regions during specific seasons.

Other categories of finds at Andernach show the movement of objects and, thus in some manner, of people, over much greater distances. Marine mollusk shells (*Homalopoma sanguineum, Dentalium*) show contact between the Central Rhineland and the southern French Atlantic or even Mediterranean coast, a distance of some 800–1,000 km. Possibly contact was along the axis provided by the Rhine-Rhône river systems; alternatively, movement could have been along the northern edge of the upland zone, traversing the region of origin of some of the Cretaceous flint. A few specimens of *Tympanotonos* and *Pirenella plicata* from C 1 and C 4 identified as fossils from Lower Miocene deposits in the Mainz Basin suggest contact between both these concentrations and the south.

Apart from the modified marine shells, the teeth of several mammal species transformed into ornament were found at Andernach. Reindeer incisor teeth from C 1, C 2, and C 3 were cut as articulated series from the mandible by removal of their roots for use as adornment. They must have come from at least eight individuals; more than are demonstrated by material believed to derive from hunting episodes during the occupation of the site; however, the presence of removed roots shows that some specimens were certainly modified at the site. C 3 yielded three similarly modified incisor teeth of a large bovine, a taxon not otherwise present in the area of the 1979–1983 excavation, although postcranial bones of a large bovine found in C 4 suggest that these animals were sometimes hunted locally. Two perforated canine teeth (*Hirschgrandeln*) of red deer stags from C 1 may not have been produced at the site but imported from elsewhere. By contrast, many or perhaps most of the perforated canine, incisor, and premolar teeth of arctic fox were certainly manufactured at Andernach.

Whether the very long-range transport of some of the marine shell ornament reflects mobility of individual persons/human groups or exchange systems between groups is unknown.

Clearer evidence for the mobility of individual persons is provided by a detailed engraving on a slate plaque which shows that the artists were as familiar with these animals as with species hunted in the Central Rhineland. It is unlikely that seals migrated up the Rhine as far as the Neuwied Basin in view of the far greater distance from the Late Glacial coast to the Central Rhineland since no seal remains are known from the faunal assemblage. It is more probable that the animals were observed at the coast, which implies that at least some people present in the Neuwied Basin must have previously spent time there. Engravings of seals are very uncommon in the Rhineland Magdalenian and the most commonly depicted animal species are horse and mammoth, with several of the other hunted species also represented by engravings (Bosinski 1996). Rare representations of woolly rhinoceros show that both mammoth and rhinoceros were well known to the artists, but, as in the case of seals, they may have encountered or observed these megafaunal species not in the Central Rhineland, but elsewhere.

In contrast to the realistic representations of animals, the many depictions of women are executed in a very schematic fashion (Bosinski 1992; Höck 1995). The figures, without head and feet and with pronounced buttocks, are often arranged as pairs or in groups to form scenes interpreted as dancing. Female figurines, normally carved of ivory, are fashioned in the same style. In addition to the representations of animals and women are many engravings of abstract symbols, and together this rich corpus of art forms an open-site equivalent to body of artistic expression from western European Magdalenian cave sites and reflects the complex social activities which occurred at Andernach.

Conclusions

The site of Andernach must be seen as forming only one location in the extensively oriented land-use occupation strategy of highly mobile Magdalenian people. That they were in a position to occupy specific localities intensively is shown by the large amounts of diverse materials accumulated at favored locations in the landscape. The intensity of settlement probably represents a palimpsest of occupations over an appreciable length of time (several weeks to several months) due to repeated visits separated by periods of absence lasting a season or even longer.

It is possible that northern Magdalenian groups spent the shortest days and coldest part of the year in sheltered locations, such as the Central Rhine valley, with a period centered around winter the time when the "temporary sedentism" seen at Andernach would be the most appropriate survival strategy. Conversely, the probable time of their absence from the site perhaps involving social contact with other groups by traveling to other regions (as suggested by a range of exogenous materials at the site) would have been the warmest season with the longest hours of daylight, the summer. This scenario can be broadly suggested for Andernach and is supported by better seasonal evidence at the neighboring and similar site of Gönnersdorf. An alternative interpretation of the role of Andernach would see distinct groups of people inhabiting different regions traveling to the Central Rhineland, giving the site the character of an "aggregation camp." With no clear indications for the social identity of the people occupying the different Magdalenian concentrations, it may be impossible to decide which model is more plausible.

Andersson, Johan Gunnar

Magnus Fiskesjö
Department of Anthropology, Cornell University, Ithaca, NY, USA

Basic Biographical Information

Johan Gunnar Andersson (1874–1960) is an archaeologist, paleontologist, and geologist, a pioneer in Neolithic Chinese archaeology, and also famous for his involvement in the discovery of Peking man. He was born in rural Sweden and in several riveting autobiographical books (*1932*, most famously) tells the story of how he became interested in science and nature already as a young boy. He later read geology and paleontology at Uppsala University and received a doctoral degree in 1901 for his dissertation on the geology of Bear Island in the North Atlantic. Andersson participated in several other Arctic and Antarctic expeditions. In 1906 he became director of Sweden's Geological Survey and hosted the International Geological Congress in Stockholm in 1910. In 1914 he accepted an invitation to work at China's newly organized National Geological Survey (NGS) as a "mining adviser to the Chinese Government" of the young Chinese Republic founded in 1911 (Fig. 1).

From 1914 to 1925, Andersson was based in Beijing (Peking). There, he trained geologists, surveyed mining ores, and helped modernize Chinese mining. He also engaged in paleontological investigations across Northern China. Then, beginning in 1920–1921 with his sensational archaeological discoveries of China's previously unknown Neolithic, Andersson shifted decisively to archaeological field research during his last 4 years in China.

He dedicated the rest of his life to publishing the results of his Chinese research and also to the new Museum of Far Eastern Antiquities, in Stockholm, Sweden, which he opened in 1929 based on the first collections from Chinese Neolithic archaeology, which had been partaged between Sweden and China. He served as the museum's

Andersson, Johan Gunnar, Fig. 1 Johan Gunnar Andersson in the field in China, 1918 (Andersson's photographic collection, Museum of Far Eastern Antiquities, Stockholm)

first director and continued his work there after retiring in 1938. He kept writing and publishing into the 1950s, ultimately returning to his native rural home area.

Major Accomplishments

In 1920, following on years of geological and paleontological survey work, Andersson and his Chinese co-workers came across painted ceramics protruding from gulleys at Yangshao, Henan Province. Based on his knowledge of geology and stratigraphy, Andersson confirmed that they were Neolithic. Excavations were carried out the next year, with Yuan Fuli (1893–1987), another pioneer geologist-turned-archaeologist, and others (Andersson 1923). This was a sensational breakthrough, since Neolithic materials had not previously been systematically studied in a stratigraphic context in China. Yangshao later gave name to an entire period of prehistoric archaeology and sparked debate over the relationship between the previously unknown people who had created these materials and later Chinese civilizations.

Until recently, it was widely believed that the breakthrough was accidental, but recent archival research (Chen and Fiskesjö 2014) has shown that Andersson knew the time was ripe for the archaeological discovery of Chinese prehistory. He had been encouraged to pursue it by the famous archaeologist Oscar Montelius (1843–1921), who argued that China's unknown prehistory was obscured by the burden of known history, just like that of Egypt or Greece had once been.

In light of the then-current theories concerning transcontinental linkages between prehistoric cultures in eastern and central or western Eurasia and bolstered by the apparent similarities of Yangshao to Anau, Tripolje, and other comparable Eurasian sites further west, Andersson developed a major NGS-supported and Swedish-financed campaign of more excavations further west (Fiskesjö 2016). His closest Chinese colleague and superior, the British-trained geologist, polymath, and politician Ding Wenjiang (1887–1936) who was founder-director of the National Geological Survey, strongly encouraged this research and was as enthusiastic about it as "An Tesheng" (Andersson's Chinese name) himself.

His work in the provinces of Gansu and Qinghai was carried out during 1923–1924; the resulting wealth of ceramics and other prehistoric materials found forced Andersson to focus on their recovery and care. Hundreds of painted vessels and other artifacts were shipped on rafts down the Yellow River. In 1925, a Swedish-Chinese partaging agreement was made between the NGS and the China Committee now chaired by Sweden's Crown Prince (later King Gustaf VI Adolf; reigned 1950–1973), himself an archaeologist and scholar. Andersson would ship everything to Sweden, describe it, and return half to China (which he did, in seven shipments, 1927–1936). Andersson was appointed Professor

of East Asian archaeology and used the Swedish half to find the Museum of Far Eastern Antiquities, which opened in Stockholm in 1929 (see Fiskesjö and Chen 2004; Fiskesjö 2014).

Because of his museum commitments, as well as the Japanese invasion of China, Andersson could not continue his field research program in China as he had hoped. On his last trip to Asia, in 1936–1938, he conducted surveys and excavations in Sichuan, Western China; Hong Kong; and Vietnam (Andersson 1938, 1939). In retirement, Andersson focused on writing up his research, in large part published in the *Bulletin of the Museum of Far Eastern Antiquities BMFEA* since 1929 (Andersson 1943; also *BMFEA* volumes 17, 18, 19, and more) and with parts of this work delegated to others (e.g., Palmgren 1934; Sommarström 1956).

Later, the returned Chinese materials were lost, probably in the war (including priceless human ceramic figures that remain unparalleled despite the phenomenal development of Chinese archaeology since Andersson's time) – as were the Peking man (*Homo erectus*) fossils excavated from 1921 onward at the Zhoukoudian site, near Beijing, the potential value of which had been pinpointed by Andersson. Strangely, the disappearance of the Peking man fossils has attracted much more attention than the loss of the first Neolithic treasures (Fiskesjö 2010) even if, of course, a whole Neolithic archaeology has developed since Andersson's breakthrough.

Today, the Museum of Far Eastern Antiquities still contains vast unstudied materials. While Andersson originally envisioned it as an international center for East Asian archaeology, the prehistoric materials were increasingly marginalized in favor of later-period arts. Even Andersson, who had lamented the destructive effect of looting for artifacts in the wake of his own field research, became increasingly entangled with collectors and dealers (Johansson 2012; Fiskesjö 2014). The reasons for this shift include China's isolation under Mao and also an absence of disciples to pursue Andersson's path. Most notably, Andersson recommended the talented Folke Bergman (1902–1946) as a field archaeologist to the expeditions of the Swedish geographer and explorer Sven Hedin (1865–1952), but Bergman died prematurely, and Hedin's expeditions were also interrupted by war and other factors.

Johan Gunnar Andersson's pioneer role in Chinese archaeology was made possible by his insights and skills from geology and paleontology, just as archaeology itself once emerged on this same trajectory. Andersson's genius and main accomplishments were in the spirited and creative application of these insights to the trailblazing discoveries of the prehistory of East Asia, accomplished in collaboration with his Chinese colleagues. Andersson is famous above all as a key pioneer of (Neolithic) Chinese archaeology, as the founder of Sweden's Museum of Far Eastern Antiquities, and also as a prominent geologist, paleontologist, polar explorer, and writer. Less well known is the fact that apart from his numerous scientific papers and books in all these fields, this polymath also, in his last years, published a 1,200-page history of exploration, denouncing the harm done to indigenous peoples through European colonialism and conquest (Andersson 1953).

Andes: High-Altitude Archaeological Sites as Cultural Heritage

Johan Reinhard
National Geographic Society, Franklin, WV, USA

Introduction

Archaeological remains, predating the Spanish conquest of 1532 CE, have been found on numerous mountain summits in the Andes, including more than 100 sites above 5,200 m, with some ranging as high as 6,700 m. This is only one of the many achievements associated with the culture of the Incas – but it is unique (D'Atroy 2002). In less than a 100 years (c. 1470–1532 CE), they constructed well-built stone structures in mountains over a vast area of the Andes, encompassing the countries of Chile, Argentina, Bolivia, and Peru (Beorchia 1985, 2001) (Fig. 1). Nowhere else on earth have archaeological remains been found at such altitudes. Indeed, the heights of some structures were not even *reached* again for four centuries, and taken together, this constitutes one of the most awesome accomplishments known to us from ancient times.

The sites generally consist of stone buildings with low walls, artificial raised platforms, and simple structures that served for protection from the elements. At the base of some mountains, fairly large complexes – some with hundreds of structures – have been found that provided storage and housing facilities for participants in ceremonies carried out on the summits. The summit structures are often not impressive in size, and it is the ritual offerings, such as statues, precious textiles, foodstuffs, and in rare cases human sacrifices, which have been found in the structures that make them of such value to us today.

Extraordinarily preserved in the cold environment of the high Andes, the mummified remains of the sacrificial victims and their associated funerary offerings provide invaluable evidence for the study of the ceremonial life of the Inca

Andes: High-Altitude Archaeological Sites as Cultural Heritage, Fig. 1 Map of the central Andes with selected Inca high-altitude archaeological sites marked. (Courtesy of the National Geographic Society)

civilization. They are among the few pieces of material evidence of Inca religion that have survived the Spanish conquest and have been found in their original contexts. Unfortunately, during the last 100 years, many of the mountain-top shrines of the Incas have been destroyed by looters, and the scientific study of these sites only began in the past few decades.

Definition

The term "high altitude" has often been used by archaeologists to refer to sites found above 5,200 m. This has been a convenient way to distinguish them from lower-lying ruins with which they may, nonetheless, share many characteristics. It is also understood that ruins on a mountain only 2,000 m in altitude could still be considered "high" relative to people living over 1,000 m below.

Nonetheless, it is the high altitude of so many ruins that has captured attention, not least of all because of the great amount of energy, organization, and in some cases specialized techniques necessary for constructing and maintaining structures at such heights. Commonly, even people who have lived all their lives at c. 4,000 m (the highest that permanent villages are normally found) have difficulty in reaching, let alone working at, altitudes over 5,200 m.

A mummy can be defined as a human corpse that has had its skin preserved over its skeleton, either through natural or artificial processes. One of the things that makes Andean frozen mummies unique is their *natural* preservation. Egyptian mummies are renowned and some date back over three millennia before the Incas. However, these are usually desiccated bodies that have had their intestinal organs removed and embalming techniques utilized to help the mummification process. As rare as these ancient mummies may be, those mummies that have been naturally frozen are far more so. Thanks to their better-preserved body tissues and organs, they provide a wealth of human biological information otherwise unobtainable and enable scientists to undertake far more comprehensive studies.

Historical Background

The Spanish chroniclers described Inca offerings to the gods as including statues made of precious metals, finely woven textiles, and ceramics of distinctive Inca style, along with coca leaves, incense, food items, and alcoholic beverages. Although they also noted that offerings could involve human sacrifices, it was not until 1954 that scientists began paying serious attention to such sacrifices having taken place on mountains. That year, looters in Chile discovered the body of an Inca boy on the summit of El Plomo at c. 5,200 m. After it was recovered by archaeologists, the study of the mummy and its associated artifacts led to a collection of articles by specialists from several scientific disciplines (Mostny 1957). In 1964, the frozen body of an adult male was found by mountain climbers at 6,000 m on Mount El Toro, and in 1985, the frozen body of a seven-year-old boy was recovered from an Inca site at 5,300 m on the slopes of Aconcagua in Argentina (Schobinger 1966, 2001). The resulting studies of these mummies laid the foundation for the development of longer-term scientific excavations to be undertaken on the summits themselves during the 1990s, and this resulted in the discovery of four exceptionally preserved Inca mummies on the mountains of Ampato and Llullaillaco in Peru and Argentina, respectively (Reinhard 2005; Reinhard and Ceruti 2010) (Fig. 2).

Key Issues/Current Debates

The Andean mountain-top mummies are unusual even among the world's few "ice mummies." This is because the human sacrificial victims often would have become frozen at the time of their deaths – not after time had passed and the bodies begun undergoing decomposition. Indeed, several chroniclers described many of them as having been buried while they were still alive. On snow-laden mountains, this has allowed for an unprecedented scientific treasure – a body could be frozen with little decomposition having occurred even after the passage of five centuries (Fig. 3).

Andes: High-Altitude Archaeological Sites as Cultural Heritage, Fig. 2 An overview of the Inca ceremonial site on Mt. Llullaillaco's summit at 6,700 m. (Photo: Johan Reinhard)

There are several reasons for their excellent preservation, but the main one would have been the continuity of below-freezing temperatures at the high altitudes of Andean peaks. Scientists have noted that some humidity is necessary because the absolute absence of water causes shrinkage and embrittlement of organic materials by water loss. As Cronyn (1990: 24) noted, "the best condition for preservation is that of extreme cold – for here, since all water is turned to ice, it is inactivated without being lost and so both inorganic and organic materials are unaffected."

If volcanic ash surrounds the mummies, such as has occurred in some cases in the Andes, this also helps to inhibit the growth of bacteria, while maintaining moisture. And the rapid burial and freezing of the soil can result in a vapor barrier being created, further impeding decomposition. This unique combination of factors makes the high Andean summits excellent places for the preservation or organic material. Frozen mummies have even been recovered with their DNA perfectly intact.

At present, these high Andean sites cannot be protected and they will – sooner or later – be looted. That is a fact, one underlined by the looting that already has taken place at many of them, not to mention at thousands of tombs throughout the coastal region and highlands of western South America (Atwood 2004). Of the several dozen high-altitude sites I have seen, only a few have not been at least partially looted *already* – in the sense of items having been taken from the surface and holes dug. It is impossible to post guards on the summits or even around the mountains, which are, after all, several miles in circumference. Furthermore, mountains can be climbed from many sides, and, if situated on a border between countries, they are even harder to protect.

Several factors have combined in recent years to increase the likelihood of the sites being looted. Access has become easier as roads have penetrated throughout the Andes, in large part due to mining. Poverty and the displacement of people has increased, while at the same time the amount of money being paid on the black market for artifacts has multiplied. The number of mountain climbers has increased, gear (and its availability) has improved, and guidebooks now provide descriptions of routes up most of the mountains. It is not a matter of *if* the mountain sites will be looted, but *when*. As for the ease of destroying one of them, a single person with a stick of dynamite could be on and off the summit in less than an hour.

All of this is also taking place within the larger context of climate change. Throughout the Andes, the permanent snowline is receding, exposing ruins previously hidden from sight. This not only makes the organic materials more susceptible to decomposition, it also makes them more likely to be discovered and looted.

International Perspectives and Future Directions

Whether in a museum, in a laboratory, or in the field, research on the ritual offerings made on mountain summits continues to add to scientific knowledge while at the same time helping protect the cultural patrimony of Andean peoples. Mummies and their associated artifacts also serve as means to help the economies of local communities through avenues such as arts and crafts, museum exhibitions, and focusing government attention on their needs.

Mummies provide information that can be used to educate the world about the unique history of a remarkable ancient civilization – and point the way to others. In the imaginations of many children, mummies are second in interest only to dinosaurs, and their educational potential appears to be unlimited. A mummy is a magnet and can be used as a teaching tool on many subjects, including archaeology, geography, human biology, conservation, and the environment.

True time capsules, these frozen bodies allow a view into the past that cannot be obtained through any other means, including that of the best-preserved mummies found in other climates, such as in the deserts of Egypt (Bahn 2003). Due to their excellent preservation, finds made at high altitudes enable unique opportunities for studies ranging from the biological to the archaeological (extremely rare artifacts and among the few remaining Inca ceremonial sites which have offerings in situ). Because of the Incas' practice of making human sacrifices at sites on high mountains, the Andes region is the only one in the world with a good chance of finding frozen mummies – assuming systematic work is conducted before they are destroyed and lost to mankind forever.

In recent years, it has become clear that a frozen mummy is one of the most valuable objects to reach us from the distant past. Such mummies

will *never* stop adding to our knowledge, since technology is constantly evolving and they contain information that cuts across a wide variety of scientific disciplines, including ones as diverse as ornithology, pollen analysis, parasitology, DNA analysis, microbiology, paleopathology, odontology, prehistoric diet, and textile and pottery analysis. New information will be obtained years from now and likely to continue to be so for as long as mankind exists. Thanks to extraordinary cell preservation and advances in technology that have resulted in the reanimation of frozen cells, one day frozen mummies may no longer just be like time machines, they may *become* time machines, enabling us to recover living information from the past. It is difficult to imagine anything, however rare, that can compare with the uniqueness, complexity, and the unlimited knowledge provided by a frozen mummy.

The documentation of the mountain-top shrines and the finds made at them has combined with the development of interdisciplinary studies on frozen mummies and other organic materials to add insights into fundamental aspects of Inca ceremonial life. They have therefore not only helped deepen our knowledge of Inca civilization, but contributed to the preservation of an invaluable heritage for future generations.

Andes: Origins and Development of Agriculture

Elmo Leon
National Museum of Archaeology, Anthropology and History of Peru, Lima, Peru

Introduction

Terminal Pleistocene horticultural societies such as the Natufian complex of the Near East that domesticated wheat at c. 14,000 BCE were not alone in the world at that time. Recent interdisciplinary research show that past tropical Andean societies began to experiment with cultigens

approximately 12,000 BCE, i.e., somewhat coeval with other pristine cultures around the world.

Two main effects resulted from this early plant manipulation process. The first one was the in-crescendo guarantee of stocking staples, which ensured quasi-permanent food among ancient Andean societies. The second effect was the resulting decrease in mobility of plant manipulators, who learned to plant seeds near camps and dwelling structures, thus providing food in one place, and therefore the preference of establishing in the same place.

Andean civilizations learned not only to domesticate plants since the Terminal Pleistocene/Early Holocene but completed domestication prior to the emergence of complex societies in the third millennia BCE; so from that time, only a few "new" plants were incorporated into the Andean diet. Once the principal Andean cultigens were controlled, they were improved in quality, increased in size, and massively produced, not only during the Preceramic but also CE times, even until the Incas, who cultivated maize in impressive quantities and made this plant together with potatoes and quinoa the main staples of the Imperium.

Definition

Agriculture in the Andes is a common denominator among all cultural developments throughout this territory, from the Pacific Ocean to the humid eastern Amazonian boundary including the Upper Amazonas. From the earliest times, hunter-gatherers in the Andes learned to adapt to the complex Andean region, not only by hunting, gathering, and fishing strategies but also by experimenting with plants, i.e., horticultural assays. The in-crescendo agriculture techniques during Andean cultural developments led to Andean societies to great achievements, where plant economies were crucial for the sustenance of whole cultures and even to the Imperium of the Incas.

Among the pre-Columbian Andean plants are lowland roots and tubers such as achira (*Canna edulis*), manioc (*Manihot esculenta*), and sweet potato (*Ipomoea batatas*). These provide huge proportions of carbohydrates. Further root and tubers were also domesticated in the Andes, such as for instance, oca (*Oxalis tuberosa*), mashwa (*Tropaelum tuberosum*), and ullucu (*Ullucus tuberosus*), including probably the most popular: potato (*Solanum tuberosum*). These four high altitude plants were domesticated in southern Peru and Bolivia and display exceptionally rich values in proteins and minerals. In the Andes, pseudocereals such as quinoa (*Chenopodium quinoa*) and maize (*Zea mays*), and also legumes such as peanut (*Arachis hypogaea*), common bean (*Phaseolus vulgaris*), and lima bean (*Phaseolus lunatus*) were domesticated and became important sources of proteins, carbohydrates, and vitamins. Additional important native plants were chili-peppers (*Capsicum* sp.) and coca (*Erythroxylon coca, E. novogranatense*) (Pearsall 2008).

Ancient Andean agriculture restricts its evidence mostly to macro-remains. These are found in places where organic preservation occurs. For instance, ideal organic preservation conditions on both the Peruvian and Chilean Coast (south of 4°S) allow for detailed examination of ancient Andean plants, in order to determine both taxonomy and state of specimens (wild or domesticate). Other research avenues such as phytoliths and biochemical traces in bones help to recover data on paleodiet based on plants (Piperno and Pearsall 1998).

The world of pre-Columbian agriculture should also cover derivative evidence, such as the native knowledge of conservation techniques to generate permanent staples and improve biochemical properties (as in the case of dried maize or chuño–dried potatoes), or even the development of artificial irrigation techniques dating to 5600 BCE, such as those irrigation channels found in the valley of Zaña, which could be considered the oldest probable evidence of agricultural irrigation systems (Dillehay 2011).

When they realized that some cultivars yield higher productive resources when planted in combination, this aboriginal knowledge allowed ancient Andean people to profit from agricultural resources. This was the case for maize, common beans, and squashes, when these three plants were

cultivated together. While maize grows upwards in the middle of the field, common beans profit from the wet and shady environment, and squashes flank both plants as a protection wall. Such combination was already mentioned by Vavilov and was used in the Andes from the very beginnings of the agriculture. Apparently, there are other combinations with positive effects among other plants, such as high altitude tubers and rhizomes.

The very early peopling of the Andes seems to be almost coeval with the discovery of plant manipulation and horticultural practices that finally led to agriculture in the Andes. Calibrated radiocarbon dates of Ecuadorian phytoliths of both domesticated squashes (*Cucurbita* sp.) and gourds (*Lagenaria* sp.) push back them to approximately 10,000 BCE (Piperno and Stothert 2003). In Peru, pristine cultivars are found in the cave of El Guitarrero, a site located in the Callejon de Huaylas, an interandean and mesothermic valley at 2850 masl in the Central Andes. At that site, Tom Lynch (1980) reported a layer containing macro-remains of the already domesticated common bean (*Phaseolus vulgaris*), oca (*Oxalis tuberosum*), and chili pepper (*Capsicum* sp.) dating c. 9600 BCE. All of these finds imply that plant manipulation began around 10,000 or even 11,000 BCE, i.e., within the Younger Dryas, virtually the last ice age.

Recent archaeological research conducted by Tom Dillehay on the Northern Coast of Peru (Zaña valley) shed light onto very early agriculture in the Central Andes. By using interdisciplinary analysis, wild peanut (*Arachis* sp.) macro-remains and starch were discovered in situ and dated to approximately 7000 BCE. Sweet potato (*Ipomoea batatas*), also an important tuber among the ancient Andean people, was domesticated around 8000 BCE, but was introduced to the Andes and later became one of the most important food sources. A wild ancestor (*Manihot flavelifolia*) of the sweet potato (*Manihot esculenta*) was likely domesticated in the Cerrado region (Southern Brasil), and then imported into the Andean area (Piperno and Pearsall 1998).

However, two plants are most representative of the Andes: potatoes and maize. The earliest potato remains were found in a site called Huaynuna, located on the Central Coast of Peru and dated to approximately 2800 BCE (Ugent et al. 1983). Don Ugent, the botanist who examined the specimens, was able to find out based on starch analysis that the domestication of potatoes likely began two (or more) millennia before, i.e., around 5000 BCE. According to experts, the domestication centers could have been located principally in Northern Bolivia, Southern Peru, and Chile.

Maize was also a key domesticated plant in the Andes. Conversely to what was believed for a long time, maize of the Andes does not come from Mesoamerica or Mexico, but rather from the same Andean region. Indeed, once wild maize seeds landed in the Andes (probably by means of birds migration), people learned to manipulate and then domesticate this plant. Independent lines of evidence support the thesis of an Andean domestication that seems to be approximately coeval with its domestication in Central America (e.g., Oaxaca, Guila Naquitz). Indeed, calibrated radiocarbon dates of archaeological sites such as Cerro Julia, Cerro Negro (Casma Valley), Rosamachay (Ayacucho), the (abovementioned) Guitarrero cave, and the recently excavated Huaca Prieta on the North Coast yield approximately 5600–4000 BCE. In this last mentioned site, Grobman et al. (2012) discovered native maize races than belong exclusively to the Central Andes. In general terms, the existence of three Preceramic races of maize, older dates, the difference among the chromosomal knots, the absence of hybridization with teosinte, and the high variety of Andean maize are the basis to affirm that there was a native Andean domesticated maize.

Some high altitude plants, such as quinoa (*Chenopodium quinoa*), an important crop found at the site of Jiskaurimoko in the southern Andean plateau (Lake Titicaca environment), were already domesticated and dated to c. 2000 BCE. However, wild *Chenopodium* has been found in excavations in some caves of the Central Andean plateau dating back to approximately 7000 BCE.

Historical Background

The scientific interest in pre-Columbian agriculture in the Andes goes back at least to the end of the nineteenth and beginning of the twentieth century, with the pioneer ethnobotanical research of W. Safford, who was able to examine some botanical remains from the early archaeological field research in Peru. Also, John Harschberger analyzed botanical remains from sites like Pachacamac and proposed, based on both starch and plant morphologies that the evolution and domestication process took place within the Andean region.

In the first half of the twentieth century, works like those of Eugenio Yacovleff and Fortunato Herrera were veritable efforts in capturing all available data related to plant remains and agriculture from ancient Peru.

Richard MacNeish took another step with his ethnobotanical project in the Ayacucho basin. He intended to record all possible plant remains from Preceramic times, from a series of caves and sites in the central Andes. From that time on, in-crescendo interests in recording this kind of data have been present, and therefore projects usually incorporate this type of approach in order to document plant occurrences and development of ancient Andean agriculture. Extensive reports, such as that on "Los Gavilanes," a Preceramic site where huge maize storage holes were found by Duccio Bonavia (1982), are clear efforts towards a reconstruction of ancient plant management in the Central Andes.

On the other hand, archaeologists and other researchers discovered some key technologies that contributed to provide stable and regular food resources to the past Andean societies from the earliest times. From the Middle Holocene to the Inca time, people built, for example, complex systems of irrigation, aqueducts, and raised fields, especially in Ecuador, Peru, and Bolivia (Farrington 1980; Denevan et al. 1987; Donkin 1979; Erickson 2000; Lane 2009). High complex civilizations such as Chimu or Tiahuanaco were able to develop practical and efficient artificial systems to improve water sourcing and management. Puquios (holes to extract water from the underground) even made it possible to live in the desert, as did the Nazca some 1500 years ago (Schreiber and Lancho 2006). Recent approaches towards an integral understanding of ancient agriculture in the Andes involve, for instance, genetic analysis (Zeder et al. 2006) that uses phyto tracers to track plant origins. This and other approaches promise increasing data, leading to a better understanding of Pre-Columbian Andean agriculture.

Key Issues/Current Debates

Key issues and debates around Andean domestication are quite rich and numerous. There is discussion about the character and particularity of the plant domestication process in the Andes, the link between paleoclimatology and pre-Columbian agriculture, the timing of the Early Holocene gardening, the human manipulation of plants since the very begin of the Holocene, the phytogenetic relations among Andean plants, the biochemical properties of Andean plants, and the characterization of the agriculture technology (including channels, dams, artificial irrigation, raised fields, etc).

International Perspectives

Ancient Andean agriculture is relevant because of its exclusivity. In fact, potatoes, maize, quinoa, and other important food plants were domesticated and cultivated in the Andes once early people settled this territory, with no other contacts such as in Eurasia. These plants were therefore exclusive to the Andes, and once this area was conquered, they were exported to the world. Therefore, research is to be conducted on some key topics that will contribute to the study of worldwide parallel plant domestication processes, genetic markers (phytogenetic), and biochemical properties of the principal plants of the Andes.

Also, the precocious character of Andean domestication of plants should be radiometrically updated in order to assess the actual time depth in comparison to other worldwide histories. This implicates not only overseas interests but also

the Andean community, as the Andes are shared by six countries.

Future Directions

There are many number of difficulties regarding the destiny of ancient agriculture in the Andes, especially in moving towards a holistic view and incorporating them into current life. Probably the most important is the role of plant diversity in the Andes as a potential bioresource, not only for the Andes but also for the whole world. Ancient Andean people were able to domesticate and profit from the high potential botanical diversity. Hence, it could be a matter of research to learn about opportunities from the past and use them in the present. High protein-content tubers and grains once cultivated in the high Andes are virtually the feed reserve for the future. Another issue for future direction is the recovery of ancient efficient agricultural technologies that were developed in the Andes in the past. There are a number of studies showing the outstanding productivity and harmless effects in applying this native technology to agricultural issues. Finally, plants played a key role from the earliest time in the Central Andes, within the early process of the rise of the Andean civilization in the Middle Holocene some seven millennia before. Plants were not only food but also became a crucial part of ancient beliefs, myths, and legends. People of today who taste Andean food should realize that this ample assortment of plants has a very ancient history that belongs to the national identity; this is especially important during this time when gastronomy is experiencing a "boom." The correct link will fuse both issues, benefitting both the Andean past and current nations.

Andes: Prehistoric Art

Elmo Leon
National Museum of Archaeology, Anthropology and History of Peru, Lima, Peru

Introduction

Worldviews among Andean people go back to the very first inhabitants that once entered this vast and complex territory. Early on, people figured out a way to capture the inaccessible by means of material representations. From the Andean hunters, i.e., artists representing a dancing shaman and running camelids in caves, invoking natural powers, to the Inca "tokapus" (textiles containing different signs and colors) exhibited by the elite, sacred art was a link to power and control of human and natural resources.

Early in time, Andean artists were able to find a variety of raw materials to accomplish these handcrafts. Clay, metal, wood, textiles, bones, and even stone were employed and transformed into art. With a few exceptions, almost all objects of nature were represented, both without modification and modified into unreal subjects. Therefore, it is usual to find, for example, plants or animals transformed into humans and also human beings with bird attributes, etc. From the universal worldview, pre-Columbian ritual art is a common denominator of the Andean region from Colombia to Argentina, and from the early hunter gatherers to the arrival of the Spaniards, and even thereafter.

Definition

The prehistoric art of the Andes could be defined as all artistic expressions made of materials such as stone, clay, metals, textiles, wood, and bones, among others, with the purpose of capturing an image from the outside environment or even from the mind-self of the creator. Hence, there is a transfer of the subject from reality to a "captured" image contained in a space or even in an object. "Captured" or represented images played a number of roles in pre-Columbian times, from the animist goal (no complex societies) to power and propaganda issues (complex and aggregated societies).

Archaeologists usually divided pre-Columbian art objects into two categories, namely: non-portable art and portable art. While the first one involves murals, for example, cave paintings and even rock art, the second comprises portable objects made of a number of raw materials, in most cases little (to medium) in size and weighing less than the non-portable art pieces.

Although there are some particularities among pre-Columbian Andean art expressions, especially in regard to the multiple microenvironmental conditions of the whole Andean region, one can perceive some common traits, such as the constant intention of representing animals typical of the Andes (e.g., pumas, condors, snakes, frogs)

and also plants (Andean crops and tubers), human beings, and even scenes of life, such as the very famous Mochica iconography found in pottery or Colombian metal art.

From a chronological point of view, the wealth of artistic representations of pre-Columbian art in the Andes can be divided into two main groups. The first one was an early art that displayed images that reflect both the elements of the surrounding environments and individual-common internal "imagination." This kind of art usually belonged to the times of the hunter-gatherer-fisher, i.e., "non-complex" societies. However, it does not imply that "realistic" art occurs later in pre-Columbian times. In fact, human beings associated with animals are usually represented in caves and interpreted as hunting scenes. But, in some similar cases, the same image is accompanied by points and symbols that are part of the composition and complicated to interpret. That means non-complex and complex representations are associated from the earliest times.

As time went by, artistic expressions underwent complex transformations in response to their sources and intentions, usually within a state and civic frame as established components and official propaganda. Thus, archaeologists see the birth of complex scenes and symbols that became local and/or regional recurrences throughout the Andes, implying consensus and territorial domains. Indeed, it was the time of the second "later" art in the Andes. Examples for such an art could be the Inca human figurines found in some fertility rites, such as the "capacocha" in the high mountains of the Andes, and also textile flags of banners representing jaguar-snake-human being gods of the Chavin culture some 2,500 years ago.

Once the Europeans landed in the Andes, pre-Columbian art persisted, despite the occidental rules against all native artistic expressions as a part of the conquerors' domination plan. A very interesting example is the continuity in rock art paintings of Lachay (Near Lima, Peru), where one can see pre-Columbian designs in association with images of Jesus Christ on the same wall cave (Bonavia 1999).

Historical Background

Let us now mention some relevant passages of pre-Columbian art of the Andes. Once they arrived in the Andes, non-complex civilizations began to paint and engrave rocks and caves. In fact, the need to create art goes back to the earliest times, i.e., the Paleoindian period. Parenti (1996), for instance, found two red parallel lines in association with a hearth in Boqueirao da Pedra Furada (Piaui, Brazil) dated to 17 kyr BP. Later, Jean Guffroy (1999), in a synthesis of the Central Andean rock paintings and engravings, proposed that indeed this is a particular Andean tradition than belongs to the Central Andean region, including southern Peru and probably northern Chile and NW Argentina.

Early rock art usually displays hunting scenes, but there are also some other "common denominators," such as the "negative hands," a tradition shared by a number of regions as Peru, Argentina, Bolivia, and Chile. These are quite similar to those made in Europe by Solutreans some 20 kyr ago. The "negative hands" are prints of hand silhouettes, usually in red or black colors, possibly representing children initiation rituals. Later, rupestrian art was also practiced by cultures as the Cupisnique (100 BCE–1 CE) or even the Recuay (100–700 CE) in Central Peru.

Cave paintings were made throughout the Andes. In northern Chile, for example, research around this art has been recently updated and summarized by Sepúlveda et al. (2010). They point out that most of the representations in an initial time span, c. 2000 BCE–1 CE, address themes related to hunter-gatherer activities and, in a second time span, caravans of camelids, a typical symbol of the Southern Andes that implies commerce and trade.

As explained above, Andean people such as the Chinchorro from the northern Chilean desert manufactured grave goods, shell and bone necklaces, and pendants dating back 5,000 years. Among these remains, archaeologists were able to find colored pigments and small vegetable brushes that were probably used to paint their

bodies (Arriaza et al. 2008). Grave goods representing ornaments destined to be a companion of the death person are typical, even from the Middle Holocene.

One of the mobile arts typical of the Andean cultures is the decorated pottery. From the very beginning, Andean people learned to paint, engrave, and model clay. Very early decorated bowls (c. 3800 BCE) were manufactured by the Valdivia culture, which was located in the southwest of Ecuador. These vessels were usually finished with a burnished red slip and decorated on their exterior surfaces with incised geometric motifs. The Valdivia potters also made figurines representing male and female individuals for ritualistic purposes (Raymond 2008). In Peru, for example, in some very early archaeological sites such as Caral, Chupacigarro, and Áspero, dating from c. 3500 BCE, archaeologists found miniature idols made of clay that are believed to have relationships with rituals.

Metal handcrafts also occurred relatively early in the Andes. At Jiskairumoko on the southern Altiplano, a necklace composed of gold beads has been found in a context dating to c. 2200 BCE (Aldenderfer 2008). Later in time, gold ornaments, such as from the Kuntur Wasi, were made exclusively to accompany priests and elite persons. But later cultures, mostly from the beginning of our era, achieved quite impressive metal pieces, not only from Peru but especially from Colombia, among such cultures as Nariño, Tairona, Muiscas, etc. pre-Columbian metal workers learned to work mostly gold, silver, and copper. They were not able to discover iron.

Textiles and fabrics are also one of the most impressive and finest manifestations of Andean pre-Columbian art. This type of organic remains is almost perfectly preserved along the coastal desert because of the dry climatic conditions. Textile handcrafts have their origins in Early Holocene basketry; techniques learned from that time later applied to weaving. For example, on the northern coast of Peru in a site called Huaca Prieta, a c. 3000 BCE, cotton textile was found. As with other materials, textiles were conceived not only for practical and dressing purposes but also for beliefs and religion. Textiles of Huaca Prieta display, for example, a design of a condor and a snake within its belt, two of the most represented animals among the Andean iconography. Because of their sophisticated techniques and bright colors, the Paracas have some of the most impressive textile art. Thousands of mantles, dresses, and embroideries are wonderfully preserved within the Desert of Ica, immediately south of Lima. These "masterpieces" are believed to cover and wrap mummies in a way that bundles and contains these human remains and offerings of various types and raw materials. Archaeologists interpret the "excessive time" invested in their elaboration as the result of ancestor worship in the past.

Another important raw material is stone, so, for example, lithic sculptures are also a particularly developed art by Ancient Andean people. From north to south, we can mention some outstanding examples, such as the stellae made by the San Agustin culture in Colombia (representing priests or shamans and dating CE 1–1200), the Chavin (1000–100 BCE) stone sculptures (representing zoomorphic and phytomorphic beings, including anthropomorphic human beings), the Recuay (100–800 CE) mourning lapidae, and the impressive Pucara (1000–100 BCE) and Tiahuanaco (100 BCE–1200 CE) monoliths undoubtedly associated with ancient gods and beliefs. Among these, we can mention the Bennett's monolith, currently a symbol of the Tiahuanaco culture. Not considered art but no less impressive are the sculpted wall stones of Inca buildings, e.g., Sacsayhuaman (Cuzco). The perfect fit of their outlines, used as "block puzzles" to erect walls, led archaeologists to think Incas were aware of masonry techniques and used sophisticated procedures to transform stone forms to some degree.

Finally, idols and other modeled artistic items of wood and bone were also created by a number of cultures of the Andes. This is the case for the figurines of the Peruvian north coast cultures, or the beautiful Inca beakers of wood called "Kero," which were decorated with rhombic designs and flowers that were actually Inca patterns, indicating regional domination.

Key Issues/Current Debates

Among the most fascinating debates on pre-Columbian art in the Andes, there is discussion on the exclusively "unique" character of some selected pieces. Indeed, all Andean pieces share common traits, such as modular bodies of anthropomorphic representations or shamanic personages, but in some cases there are distinctive pieces that distinguish themselves from the others. Stone sculptures such as the "Estela Raimondi" (Chavin Culture, c. 400 BCE) or the Bennett monolith (c. 200–500 CE) are unique pre-Columbian legacies to Peru and Bolivia, respectively. Hence, pre-Columbian art could also be considered national symbols in Andean countries.

Another key issue in pre-Columbian Andean art is the techniques that were employed. Tiny metal filigrees, helicoidally made wooden sticks, highly elaborated textiles, or stones that seem to have been "smelted" still remain enigmatic from the technical point of view. Archaeologists, aided by other colleagues from a variety of research fields, try to reconstruct some *chaine operatoires* that lead to this kind of superb technical-artistic results.

We know that in the Andes, there were no writing systems, and yet there were accounting devices and possible ideograms. So, are we able to recognize one artist or a family/group of them when assessing an artistic work? Chris Donnan proposed that among the Mochica potters, there were actual artists who were painters and exclusively devoted their time to the fine painting of ritual pottery. However, we lack further data and studies of other cultures to test if this was a regular trait of ancient Cultures of the Andes.

Pre-Columbian Andean art of complex civilizations is usually conceived to enhance power and legitimacy of some cultures "above" others. Yet the conceptual relationship of "art-power" in the Andes as an establishment is in some cases a matter of debate when chemical-physical sciences are applied, so that, for instance, some highly decorated Nasca vessels (CE 1–650) from Ica (south of Lima) were also used for food purposes and not only as grave goods.

But were archaeologists able to find the ancient artistic workshops that were agglomerated by these creative minds? The answer is "unfortunately no." Most research addresses graves, simply because the luxurious contents attract media and people, which helps to maintain and improve research budgets. As seen, archaeologists need to apply a rather holistic approach in order to get a more complete overview from the past art in the Andes.

International Perspectives

Indeed, there is great potential in ancient Andean art, because of its uniqueness, palette-rich expressions, high technical quality, outstanding manufacture, and combined colors. Its abstract and lineal modulation, in contrast to other world ancient arts such as the Roman Empire or even Attica, are typical of the Andes. Furthermore, the nature and special combination of structure and colors, for instance, gold-cinnabar-turquoise, make such a visual impact, surely in ancient and even in modern times. However, technical and contextual data are still lacking.

Future Directions

A post-processual perspective is needed within this fascinating issue of pre-Columbian Andean art in order to improve our knowledge on this issue. Round tables with interdisciplinary participation would highly benefit our understanding of the how, reasons why, and role of ancient Andean art among not only elite but also common populations.

Andes: Prehistoric Period

Elmo Leon
National Museum of Archaeology, Anthropology and History of Peru, Lima, Peru

Introduction

After the Last Glacial Maximum (LGM), immigrants from Asia and probably other parts of the world entered the American continent. Once established in this ample territory, some settled in North America, while others peopled the Pacific shore, intra-mountain areas, and Amazonia of South America. Some people remained on the western side of South America, a territory whose common denominator is the Andean chain. Although it is difficult to say why Ice Age people decided to stay in the Andes, one possible reason is (and was) its extremely diverse and rich ecological environment (Lavallée 1999). From west to east, the tropical warm waters in the north, cold currents in the south, temperate and microthermal Interandean chain, the cold southern Altiplano, and the evergreen Amazonia certainly provided a number of resources for food and raw materials, depending on seasonal productivity. Besides, a combination of natural rivers resulted in a cool and extremely rich ocean stream (the Peruvian or Humboldt stream). Upwelling waters have made a huge number of fishes and mollusks constantly available to humans living along the Peruvian and Chilean coast, especially from about 5,000 BP. Some archaeologists believe these were the basis of the Andean civilization (Dillehay 2000).

From a global perspective, Andean prehistory seems to have some constants, such as extreme internal cohesion among ethnic groups, strong interchange links, reciprocity, communal labor and sense, authority and vertical power, fixed traditions, deep beliefs, and a special commotion in front of natural events. These are key in assessing material culture in response to ancient Andean behaviors.

Definition

By convention, the prehistory of the Andes lasted from the very early peopling of this region at about 16,000 BP, until the arrival of the Spaniards at the beginning of the sixteenth century. From the start, early human settlers who entered the Andes inhabited a number of ecotones, from the Pacific Ocean shores of South America's western flank to above 4,000 m above sea level (masl), high in the Andes Mountains. Archaeologists believe that by that time, the Amazonian region bordering the Andes was also inhabited.

The development of different cultural complexes within the Andean region occurred under a scenario of changing environmental conditions. The initial population was coeval with the time span after the LGM that is marked by glacial advances and inversions, until the Younger Dryas (YD) event approximately 13,000 BP (León 2007). People were hunters, gatherers,

fishers, and scavengers and lived in both camps and caves. From that time, some locations of the Central Andean region experienced a socioeconomic boom due to two key events. The first event was the premature invention of horticulture, especially based on squashes and likely a short time after the YD. Next, among other important plants, chilies (*Capsicum* sp.), peanuts (*Arachis hypogaea*), and beans (*P. vulgaris*, *P. lunatus*) were domesticated from the time of the glacial-Holocene transition at 12,000 BP. The second key event (as a consequence) is that some groups became less mobile after the Early Holocene, and thus the sedentary process that finally led to the rise of Andean civilization was triggered (Bonavia 1991; Lavallée 1999; Dillehay 2000).

Socioeconomic developments within the Andes were not coeval. The rise of complex societies within this broad area seems to have occurred earlier, and originated in the Central region, especially from the coast of Ecuador and Northern–Central Peru.

The whole Central Andean development, founded on very early agriculture, camelid domestication, and quasi-permanent seafood resources, probably lead to internal social aggregation, differentiation, and discrete hierarchies at around 6,000 BP. Emergent complex societies generated ritual paraphernalia and a "sacred world" that commanded a series of socioeconomic developments. Therefore, ornaments decorated with a typical Andean iconography were manufactured in response to the different gods that were worshipped.

The reorganization and establishment of the cool sea of the Peruvian stream region resulted in both a quasi-permanent and invariable climate and richness in seafood resources (including fish and mollusks) that complemented the horticulture already being practiced. This time span corresponds to the Maximum Holocene, when climate was warm and wet. Soon after 6,000 BP, people were able to build monuments devoted to ritual activities, probably linked to economic endeavors. Whereas pottery occurred in Peru around 4,600 BP, it dates to 7,000 BP in Ecuador. Monumental architecture experienced a singular emergence after that time. Archaeologists were able to identify at least three architectonical traditions. The first consisted of truncated platforms, stairways, and ramps; the second displayed courtyards, rooms, and a subterranean ventilation duct for fire offerings; and the last one was composed of a u-shaped building typical for the Central Coast of the Peruvian Andes.

"Periphery" regions to the Central Andean Region underwent cultural changes to become complex societies somewhat later. However, the premature techniques discovered in some circumstances appear to be extremely early. For example, this is the case for the mummies of the Chinchorro culture located on the coast of Northern Chile and Southern Peru and dating to approximately 7,000 BP. Even within the Middle Holocene, people of this culture were able to recognize that organic remains were perfectly preserved when exposed to very dry conditions of the Atacama Desert. Noncentral Andean societies also contributed with some key food resources, such as the potatoes, sweet potatoes, or peanuts that, once introduced among complex civilizations, became a key factor in their development. These are undoubtedly plants that were domesticated in the Oriental Andes or even in the Amazonian region and then introduced to the Andes.

Central Andean prehistory is one of the most attractive research issues, both to national and international archaeologists. This is not due to the former occurrence of the greatest empire of the southern hemisphere, by the Incas, but to the outstanding preservation of organic remains from the very earliest human presence in this region.

Some 3,500 years ago, the Andean landscape witnessed the rise of the first civilization known as Chavin; this name was chosen from the Chavin de Huantar site in the Central Highland of Peru. Some archaeologists consider this cultural occurrence as the very first horizon, based on the spread of icons such as jaguars, condors, and snakes, always altered and mixed with traits of human beings. This iconography is found from Northern to Southern Peru, covering more than 500 km, thus implying all regions within this radius were part of the Chavin culture, i.e., first horizon of the Central Andes. However, it must be kept in mind that almost all "Chavin traits" are not local but

rather imported. The Archaic or Late Preceramic public buildings addressed above came from both the Coast and Highland and are present in Chavin de Huantar. Also, some Amazonian animals such as caimans are key icons within the Chavin iconography. The probable pilgrimage into the cult center included paraphernalia and even inhalation of hallucinogens by priests. This time was based on religious beliefs in Chavin, and thus archaeologists propose that people were differentiated between the elite, composed of administrators and priests, and common people and servants.

The CE opening time span is coeval with the dissolution of the Chavin cult and occurrence of a series of regional cultures on both the Coast and Highland regions of the Central Andes. At that time, experts consider that states were established and an "essor" of development of complex societies took place. It was also the time of magnificent development of art in a number of raw materials, from pottery to textiles to metals such as gold, silver, and copper. In general terms, ornaments were conceived as representations of the ritualistic worship of the Andean god. Cultures of the Vicus, Mochica, Nazca, Recuay, and Cajamarca are representative of the time from 100 BCE to 600 CE. Sites display a series of forms from simple dwelling structures to ritual temples. One interesting difference is that northern buildings are usually huge and monumental, in contrast with the Southern Coast structures that are smaller.

The next period lasting from CE 600 to 1,000 witnessed a new cultural fusion, again by means of a belief in a god. This god seems to be a human being, holding a trophy head in one hand and a (sacrificial) knife in the other. Its representation spread throughout the Central Andean region, similar to the Chavin cult. Archaeologists have labeled this time span as the Middle Horizon or (by most experts) the Huari Empire. There are discrete differences when comparing the Huari god with the one of the Tiahuanaco culture (Bolivia), so there might have been some interaction between these two coeval cultures. The Huari Empire developed a complex road system that covered key places from the highest Andean mountains to the coastal shores facing the Pacific Ocean. These were further improved by the Inca Empire some millennium later. The Huari were also able to plan and construct actual orthogonal "cities," organized by administrative centers, public buildings, fortifications, ceremonial temples, and even domestic villages. Lama caravans were also a dynamic means of communication and wares interchange with other populations across the Andes.

The internal atomization of the Huari Empire leads again to a regional independence and the reactivation of local societies, not only where former ones existed, but in a number of other localities. For instance, the Chimu Kingdom ruled over the Northern Coast of Peru and was able to build the Americas' biggest "city" of mud and also the most delicate and wonderful metal handcrafts of the Central Andes. At the same time, the Huanca culture inhabited the highest mountains in Central Peru at over 4,000 masl, dominating Andean resources and the side effects of high-altitude living. Other cultures from that time achieved high quality in the manufacture of different wares and arts that in most cases were related to sacred purposes.

Finally, the Incas represent the crown of c. 14,000 Andean prehistoric development. According to historical sources, Imperial Inca development lasted only about 70 years. However, radiocarbon data seems to indicate that the Inca origins date back to at least the fourteenth-century CE. Spreading from Cuzco, they reached quite far, from Colombia to Chile and Argentina along the Pacific Ocean shore, wherever the Andean mountain chain was present. The Incas based their culture on principles such as the royal panaca (elite family ties) and a dual system of conceptualizing the world. Their paraphernalia were simply expressions of an impressive power. They conquered a series of cultures inhabiting the Andes not only by means of force but usually also by reciprocity and a smart system of interrelations. They also profited and improved the already implemented connection web throughout the Andes built by the Huari Empire, and introduced some Inca logos, such as the cross-like shape

(Chacana) and the trapezoid window typical of the Inca occurrence.

Periphery history is somewhat dissimilar, but important to include here to complete a broad intercontinental panorama on the archaeologies of the Andes. In Northwest Argentina, for example, most cultures are recognized by a dependence on agricultural crops such as maize and other tubers and grains, as well as household residential dwellings where people devoted time to economic activities such as agriculture and, at times, ritual ceremonies (Leoni and Acuto 2008). Also, in western Ecuador, permanent settlements were established by 3,500–3,000 BCE with antecedents being low, mobile people from the Las Vegas culture from 8,500 to 4,600 BCE (Raymond 2008). From the same country, phytoliths of squashes are dated to 10,000 BCE and maize to 6,000 BCE. These, together with the Peruvian botanical remains, are very early evidence of Early to Middle Holocene plant domestication of the Central Andes. Further north in Colombia, a number of cultures also developed, but they are known in some cases by their stonework (e.g., the San Agustin culture with its lithic stelae), and mostly by their wonderful metal art, as in the Muisca, Calima, Tairona, or Tumaco cultures.

The southern Altiplano area around the Titicaca Lake deserves special mention. After approximately 3,000 BCE, people settled this high-altitude region. Pukara and Kaluyu cultures are representatives of the first millennium BCE. Archaeologists recognize the importance of the Tiahuanaco culture at the end of that time span; it was actually a former state, based on religious beliefs that centered on a human-looking god who held a trophy head and a ceremonial knife in his hands. The Tiahuanaco people were recognized by their stone art and monuments. The Tiahuanaco center is an impressive center with massive stonework in the form of remarkable pyramids and platforms. Lama caravans for transporting goods are also uniquely typical for this culture. Multiproxy studies show that by that time, pilgrimage and immigration into and out of the center were quite frequent (Silverman and Isbell 2008).

Historical Background

The history of archaeological research in the Andes shares four similar and almost coeval periods (Politis and Alberti 2005). The first period goes back to the time after the Spanish arrival, when priests, administrators, and other Spaniards gave accounts of the newly conquered territories and ancient heritage. The second period includes reports of the voyagers of the seventeenth and eighteenth centuries, within the context of both the illustration and romantic years ending with the new rising Andean nations. There is a third period when scientific research begins, approximately by the middle of the nineteenth century. In Colombia, for instance, the German anthropologist Adolf Bastian made an exhaustive list of Colombian archaeological sites published in 1878; this was continued by Vicente Restrepo in 1898. In Ecuador, pioneers such as Jacinto Jijón Caamaño, Federico Gonzáles, and Otto von Buchwald also reported the first archaeological studies at the end of the nineteenth century. In Peru, Mariano Eduardo de Rivero was able to make the first archaeological collection and thus founded the national museum. Later, Wilhelm Reiss and Adolph Stuebel conducted the first scientific excavations in Ancón by the late nineteenth century. A fourth and final period started around the start of the twentieth century, with scientific research in both field and labor. In Ecuador, for example, George Dorsell, Marshall Saville, and Paul Rivet were remarkable during the first decades. One scholar who made a series of seminal contributions not only in Ecuador but also in Peru and Chile was a German, Max Uhle. This is why some consider him as the father of Peruvian archaeology. Uhle excavated in the Pachacamac Sanctuary, near Lima, Peru, and proposed the very first archaeological sequence for Peruvian archaeology based on the stratigraphy of this sanctuary. Another relevant scholar was Julio Tello, who excavated a number of archaeological sites throughout Peru, thus providing quite important collections that now comprise the national museum. Other scientific expeditions, especially from the United States, conducted a research in

Peru, laying the groundwork for the next generations. A pivotal sequence was proposed, based on the team of the famous Viru project in Northern Peru. The 1960s witnessed the emergence of interdisciplinary research that opened a new age, allowing important issues, from botanical to paleoenvironmental in nature, to be addressed. Up to 2012, there are regular projects that include this type of approach and invite not only Andean but also international archaeologists to contribute to our knowledge of Andean archaeology.

Key Issues/Current Debates

The Andean archaeology of the twenty-first century especially incorporates international debates on inclusive archaeology, gender anthropology, expedient/complex technologies, paleoenvironment (i.e., past climate change impact on ancient Andean civilizations), effects of archaeometrical contributions, radiocarbon calibrations, Andean household archaeology, *chaine operatoire* approaches, and external problems such as public archaeology. All these topics are debated and included in Andean archaeology to improve our knowledge of this subject.

International Perspectives

Andean archaeology contains issues attractive to international research teams. One such issue is the wonderful and almost perfect conservation of organic remains in the Atacama Desert that make possible high-resolution reconstructions in different perspectives. Good tissue preservations are also ideal for mummy conservation. The sea as a food provider for ancient people is also quite an interesting issue, especially because of the richness of its waters.

Future Directions

Research on Andean archaeology is a suitable and promising issue in every nation of the Andes, and national and international archaeologists have conducted it (Lane 2012). It provides not only a partial portion of the history of almost half of the countries in South America but also a sense of integration, because of the general homogeneity of ancient cultures of the Andes. A good example is the Inca road that links literally the whole Andes. The Inca road system was conceived and constructed over the whole Andean territory for the purpose of communication and ware transport and is being seen as the main link among modern Andean countries.

On the other side, governments also see the history of the ancient cultures of the Andes as a common denominator for integration. Andean countries share a similar past and so have an experience of permanent interchange from the earliest times.

Andean archaeology should also see an opening for applying new theoretical frames by relating, for example, the past roles of women, minorities, domestic activities, and landscape archaeology. Every nation has its challenges in this task.

Andron

Fiona Hobden
Archaeology, Classics and Egyptology, University of Liverpool, Liverpool, Merseyside, UK

Introduction

Andron (plural, *andrones*) is the name given by modern scholars to rooms excavated at sites from ancient Greece that combine a number of distinctive architectural features. These include a near-square layout with walls approximately 4.5 or 6.5 m in length; an offset doorway; a raised border platform; a central depression floored with plain or colored cement or plaster, or inlaid with pebbles or tiled mosaic; channels or guttering for drainage; and colored plastered walls (Nevett 2010: 47). Archaeological analyses place basic forms of these rooms at sanctuaries during the Archaic period, for example, at Perachora's Heraion and the sanctuary of Apollo Delios on Paros (Bergquist 1990: 38). Later, while continuing to appear at ritual-civic sites, the increasingly elaborate *andron* became commonplace, if not standard, in Classical and Hellenistic houses. Olynthus provides the majority of evidence for the domestic *andron* in the late fifth and fourth centuries BCE, where it has been identified in a third of the excavated houses (see Cahill 2002: 74–146). While the record for smaller domestic units at Delos and in the rural demes of Attica further emphasizes that the *andron* was non-pervasive and was possibly absent from the majority of households (Trümper 2005: 119; Nevett 2005: 88, 93), the room does appear at Greek settlements across the Mediterranean (Nevett 1999: 80–126, 127, 138, 142, 153). However, sometimes the designation "*andron*" may be debatable. Thus, at the Hellenistic House of the Ptolemaic Coins in New Halos, the raised platform can be indicative of a storage area in the absence of other markers (Haagsma 2003: 68). Then again, distinctive architectural features were dispensable. While a number of houses at Delos contain ornate rooms with mosaic floors and elevated platforms, few of these "*andrones*" are quadrangular and none possess an offset door (Trümper 2007: 330).

Definition

The word *andron* means literally a space belonging to men. Earliest literary attestations from the fifth century BCE make it a generic "men's quarters" and a place for hospitality, including convivial gatherings that display features of the *symposion* (e.g., Aeschylus, *Agamemnon* 244; *Libations Bearers* 712). Of the architecturally distinctive room, the elaborate furnishing, extravagant decoration, and raised platform to accommodate couches, along with the provision of stepped floors and gullies to facilitate cleaning, correspond to this specific usage. However, domestic space was flexible. The *andron*, like other rooms in the Greek house, may have been occupied differently during the day, across seasons, and between owners. Daytime activity is implied, for example, by additional architectural elements. At House II in Eretria (c.400 BCE), upper columns break up an interior *andron* wall. Like external windows, this feature would maximize light and encourage circulation of air (Reber 2007: 284). As drinking was ideally staged in the evening (and those like the younger Alcibiades who reputedly reveled by day were censured for it: Lysias 14.25), this setup would most benefit

daytime users engaged in other household occupations. More broadly, the *andron* may have provided a general living area when winter weather made the courtyard uninhabitable, as suggested by Rider (1965: 249) for Hellenistic Delos. Specific finds can also suggest changing usage over time. Thus, the presence of terracotta statues and the selection of tableware in the *andron* of the House of the Comedian at Olynthus leads Cahill (2002: 140-1) to propose that the sympotic room acquired ritual functions during its lifetime, although dual usage is another possibility.

Unfortunately, finds from *andrones* are frequently sparse and inconclusive, with the result that it is often difficult to establish what activities may have taken place on the basis of artifactual evidence. At Olynthus, even sympotic furniture and paraphernalia are rare. However, the best bet for an *andron* in the House of Zoilos did yield a loom weight, an item prevalent in other parts of the house (Cahill 2002: 135). The whole ground floor may have been appropriated for household industry (cf. Nevett 1999: 71). Then again, in the front room of House AII.6 at Leucas in Acarnania, a large room decorated with painted plaster and boasting a window, a wide range of material was excavated. The presence of cooking ware, storage vessels, and fine pottery suggests that this likely *andron* space was harnessed for the production and storage of food and drink, as well as their consumption. Worktools – chisels, fishhooks, flint instruments, and an axe – were also kept in the room (Fiedler 2005: 107–10). Certainly, to return to hospitality, opportunities for dining beyond the symposion *sensu stricto* might also arise during festivals and on a daily basis. So, when Theban rebels arrive at the home of the governor they plan to assassinate, in Xenophon's *Hellenica* (5.4.7), they find him reclining on a couch with his wife seated by his side after dinner. Presumably, on the basis of this detail, they are in the *andron* (cf. Kelly Blazeby 2011: 89 for other convivial occasions involving female family members at home). Wider usage of the *andron* by other members of the household, and not just its menfolk at the symposion, is plausible.

Key Issues and Current Debates

As the place where visitors were accommodated within the house, and as space defined by its male occupants, the domestic *andron* offers special insights into the relationships between *oikos* and *polis* and between the genders. Nevett's (1999) careful study of the Olynthian record shows that here the *andron* was frequently situated near the entrance to the house, approached through the court, and sometimes through an antechamber (the pattern is replicated at some near-contemporary sites, e.g., at Athens, 1999: 90–1; Thasos, 1999: 93–4; and Halieis, 1999: 98–101). These areas might also be decorated with "coloured plaster walls, terracottas and metal ornaments" (Nevett 1999: 70), effectively marking them as a suite and setting them apart from the remainder of the house. Through their adornment, the *andron* and the areas by which it was accessed made a statement to invited guests of the householder's "social prestige" (Jameson 1990: 189), or such decoration might be a marker of "social distinction" (see Westgate 1997–98: 106). The domestic *andron* may be an indicator of broadening sympotic activity from élite circles to the moderately wealthy, but it still conveys the affluence of the household to visitors. The addition of windows on the exterior walls, however high up, might have carried this message out into the city, at every noise- and scent-filled celebration (Tsakirgis 2010: 576).

If the *andron* communicated ideas about the wealth and prestige of the household to guests, it also provided a separate and enclosed space which kept those visitors focused inwards and away from the rest of the house. For the *symposion*, this enhanced the psychological effects of being together, hot-housing the sensory pleasures of drinking wine, inhaling incense, listening to and making music, conversing and laughing, and sexual desire. For the men who gathered together in the *andron*, relationships might be negotiated through shared endeavor and consolidated via a heightened atmosphere of merriment (*euphrosyne*) and fellow-feeling (*philophrosyne*), the qualities envisaged by sympotic poets Solon of Athens (26 W) and Ion of Chios (27 W) and

manifest in parties painted on pottery like the red-figure bell-krater now at Port Sunlight (Lady Lever Art Gallery 5037: see Robertson 1987: 37–8, 96). Produced at Athens in the early fourth century, at the very time *androne*s were becoming visible in the domestic record, this mixing vessel depicts tightly packed, garlanded young men reclining on couches, their heads thrown back in song, as a young boy beats the tympanum and a woman dances (or plays an *aulos*: the instrument is visible below the paint but omitted from the final composition). Presented within the confines of the body of the krater, the scene encapsulates the spirit of camaraderie and shared pleasures encountered within the enclosed space of the *andron*.

Because the men joining in the symposion might be friends or relatives or associates or co-members of a religious organization, the *andron* offers a bridge between the "private" *oikos* and the "public" sphere, as "insiders" and "outsiders" mix within its walls. Furthermore, drinking companions might be fellow citizens or political sympathizers. Connecting the rise in domestic *androne*s in particular to democratic practice and ideology, Ault (2000: 486-8) even suggests that "the domestic *andron* brought the political sphere into the domestic realm and provided a space for small groups of citizens to gather for discussion outside the public assembly, lawcourt, or *agora*" (see also Nevett 2010: 62). For *androne*s outside the domestic record, in civic-ritual sanctuaries from the Archaic period onwards, the dynamic might be reversed, as individuals confirm their social and political relationships and continue their conversations under the rubric of public celebration (Schmitt Pantel 1992). The *andron* thus not only bridges but muddies the relationship between "public" and "private" and in the process sheds light on the dynamics of the Greek city. Social bonds established there between friends might be simultaneously between colleagues in political enterprise, whether symposiasts are citizens dedicated to democratic endeavor or orchestrators of dissent.

While fostering unity among participants in the symposion, the *andron* also articulates a gender divide. This divide was both physical and ideological. Certainly, the room may have been used by different members of the household for a variety of purposes, possibly including weaving by women in the House of Zoilos (see above). Figured pottery like the Port Sunlight krater also shows women present at the *symposion*. However, such women were hired musicians or dancers, or they were *hetairai*, "female companions" who were sexually available (the two groups need not be mutually exclusive). As the fourth-century lawcourt case involving Neaera shows, a woman attending a drinking party could be branded a *hetaira* and find her status as a wife attacked ([Demosthenes] 59). In Athenian public discourse, female relatives should not be present in the *andron* during the *symposion*. By closing off the space to women in the family at certain moments, their contact with male incomers was controlled and gender relations were prescribed. To Antonaccio (2000: 532), the *gunaikonitis* "was a space where women could retreat when male visitors were present." By default, its male equivalent, the *andron* – or *andronitis* – becomes an exclusively male preserve, a space for men to occupy in the absence of women from the house. This was not a permanent segregation of the sexes, however, but a temporary impermeable division arising from social convention. The *andron* was both a space and an idea.

A

Angel, John Lawrence

Eleanna Prevedorou and Jane E. Buikstra
Center for Bioarchaeological Research, School of Human Evolution and Social Change, Arizona State University, Tempe, AZ, USA

Basic Biographical Information

J. Lawrence Angel was born on March 21, 1915, in London, England. His father, John W. Angel, was a British sculptor and his mother, Elizabeth Day Seymour, was an American classicist originating from Connecticut, USA. Angel moved to the United States with his family at the age of 13 and enrolled in the Choate School in Wallingford, Connecticut. In 1932, he entered Harvard where he obtained his A.B.. (Artium Baccalaureautus) in 1936 and his Ph.D. in anthropology in 1942. In 1937, Angel married Margaret (Peggy) Seymour Richardson, his wife of 49 years and an invaluable professional as well as personal partner.

His most influential mentors at Harvard were Clyde Kluckhohn (social anthropologist), Carleton S. Coon (physical anthropologist), and Earnest A. Hooton (physical anthropologist). As an undergraduate student, he participated in archaeological fieldwork in New Mexico, Arizona, and Georgia. His first data collection and fieldwork trip to Greece and the Eastern Mediterranean occurred between 1937 and 1939, mainly under the auspices of the American School of Classical Studies at Athens and Harvard University,

followed by ten more field trips in the Near East, focusing on Greece, Cyprus, and Turkey (1949, 1954, 1957, 1965, 1967, 1969, 1972, 1975, 1977, 1978).

Angel taught at the University of California at Berkeley (1941–1942), at the University of Minnesota (1942–1943), and at the Daniel Baugh Institute of Anatomy of the Jefferson Medical College in Philadelphia (1943–1962). He was a research associate at the University Museum of the University of Pennsylvania (1946–1962) and a civil consultant in surgical anatomy at the U.-S. Naval Hospital in Philadelphia (1957–1962). In 1962, Angel succeeded T. Dale Stewart as the Curator of Physical Anthropology at the Smithsonian Institution, National Museum of Natural History, in Washington D.C., a position he held until his death. Additionally, he was an adjunct professor at George Washington University (1962–1986) and a visiting professor of anatomy at Howard University Medical School (1965–1970).

After joining the Smithsonian, Angel also became actively involved in forensic anthropology and served as a consultant for the Federal Bureau of Investigation (FBI), the US Armed forces, and other law enforcement agencies. He joined the American Academy of Forensic Sciences (AAFS) in 1975; he became a Diplomate of the American Board of Forensic Anthropology in 1978 and served as president (1980–1985). He also taught forensic pathology at John Hopkins School of Public Health (1963–1986).

He served as secretary-treasurer (1952–1956) and as vice president (1959–1960) of the American Association of Physical Anthropologists (AAPA). He was president of the Philadelphia Anthropological Society (1946–1948), the Philadelphia Society of the Archaeological Institute of America (1949–1950), and the Anthropological Society of Washington (1974–1975). He also performed associate editor roles for the *American Anthropologist* (1946–1948), the *American Journal of Physical Anthropology* (1951–1954, 1960–1963), and *Clinical Orthopaedics* (1954–1970).

Angel died at the age of 71 at the George Washington University Hospital on November 3, 1986.

Major Accomplishments

Angel's work shows a remarkable scholarly breadth encompassing human anatomy and osteology, dental anthropology, paleopathology, paleodemography, paleoecology, longevity and biological aging, obesity, stress indicators, behavioral reconstruction, biological distance and genetic mixture, and forensic anthropology. Among these, health and disease as selective micro-evolutionary processes held a central place in his research. His enduring research interest in Greece and the Eastern Mediterranean developed early on in his career, where he literally founded the fields of physical anthropology and paleopathology.

His early work, influenced by Hooton, was typological and emphasized craniometry, as represented in his dissertation aimed at reconstructing the complex interplay of biology, culture, and the environment in the Greek world. In doing so, Angel introduced a highly contextualized approach that he termed *social biology* (Angel 1946). Throughout his career, he promoted problem-oriented, interdisciplinary anthropological research, methodological and theoretical rigor, and new methodologies, thus setting the stage for the more recently developed field of bioarchaeology.

Angel's research on hemolytic anemias and particularly on the history of thalassemia in the Eastern Mediterranean has been a landmark in paleopathology. He coined the term *porotic hyperostosis* (Angel 1966a, 1967), now widely accepted. Angel attributed *porotic* hyperostosis to thalassemia or sicklemia in the Eastern Mediterranean favoring the former due to its endemicity in that part of the world. Based on the classification of these two genetic anemias as balanced polymorphisms maintained by the heterozygote advantage against malaria, he linked the

occurrence of porotic hyperostosis in the Eastern Mediterranean to malaria, particularly *falciparum* malaria. In this regard, he developed a thoroughly ecological and regional approach to population health and disease (Angel 1971, 1975), culminated in his monograph on *The People of Lerna*.

Angel was particularly interested in paleodemographic parameters such as longevity, fecundity, and differential fertility. One of his major contributions has been his influential critique of the use of life tables from archaeological skeletal samples, emphasizing the difference between cemetery samples and living populations (Angel 1969). Angel was also a pioneer in the reconstruction of past human behavior and lifestyle through skeletal markers. The identification of the commonly observed elbow osteoarthritis in the Pre-Columbian human remains from Tranquillity (California) with spear-throwing described as "atlatl elbow" was highly influential, especially in linking osteoarthritis to a specific activity (Angel 1966b). His contextualized approach to behavioral reconstruction was further established in his work on the life stresses of slavery for the African American ironworkers at the Catoctin Furnace Cemetery with J. O. Kelley during the last decade of his life.

Angel received the Pomerance Medal of the Archaeological Institute of America (1983), the Physical Anthropology Section award of the AAFS (1984, 1986), and the Distinguished Service Medal of the American Anthropological Association (AAA) (1986). The AAPA organized and published a symposium in his honor (1979). Posthumously (1987), a memorial session was held at the AAA annual meeting, followed by an edited volume (Buikstra 1990). Since 1992, the Wiener Laboratory of the American School of Classical Studies at Athens has regularly awarded the J. Lawrence Angel Fellowship in human skeletal studies.

Introduction

The domestication of herding animals and the development of pastoralist societies have played a key role in human economic, ecological, and social history (Dyson-Hudson and Dyson-Hudson 1980). Pastoralism supports substantial human populations in Eurasia, Africa, and South America, and both pastoralists and other farmers still rely predominantly on the few animal species that were domesticated in the early to mid-Holocene. Understanding changing human-animal relations with domestication and the development of pastoralism provides insights into the biodiversity of the animals on which contemporary pastoralists rely, the history of milk-drinking, and the coevolution of humans and domestic animals. Archaeology provides broad perspectives on pastoral societies as complex and flexible social constructs, as forms of risk management, and as resilient systems evolved over millennia to help people to cope with aridity, climatic changes, and environmental extremes.

Definition

Conceptual Framework

Collaboration among archaeologists, ecologists, and molecular biologists has resulted in the development of a new conceptual framework for understanding the emergence and multiple dimensions of pastoralism. Pastoralism is defined here as a social and economic system in which people move domestic animals to pasture and rely on spatial mobility for survival (Dyson-Hudson and Dyson-Hudson 1980; Wendrich and Barnard 2008). Pastoralists also emphasize the social and symbolic role of domestic animals (Marshall and Weissbrod 2011). They thrive in environments where climate and topography constrain agricultural production such as deserts, semiarid plains, mountains, and tundras. Although pastoralists often complement their livestock-based economy with other productive tasks such as cultivation, exchange, trade, fishing, hunting, and gathering, the needs of their herds override other considerations. People's roles as herders and pastoralists are also fundamental to the construction of individual and group identities in pastoral societies. Pastoralism in this sense is more than an economic activity and includes ecological, social, political, and ideological dimensions.

Pastoralists depend on a range of herd animals including sheep (*Ovis aries*), goats (*Capra hircus*), taurine cattle (*Bos taurus*), humped cattle (*Bos indicus*), horses (*Equus caballus*), donkeys (*Equus asinus*), llamas (*Lama glama*), alpacas (*Vicugna pacos*), dromedaries (*Camelus dromedarius*), Bactrian camels (*Camelus bactrianus*), yaks (*Bos grunniens*), or reindeer (*Rangifer tarandus*) that were domesticated between 12,000 and 4000 years ago. Many of them were domesticated multiple times, and the circumstances in which different taxa were domesticated vary widely. Animal domestication is seen here as a microevolutionary process resulting from long-term coevolutionary relations between people and animals in humanly modified habitats (Zeder 2011). Microevolution in anthropogenic habitats and management of animals lead to selection away from wild genotypes and phenotypes. The degree to which people and animals depended on each other varied greatly. Animal domestication was a slow process, and long-term gene flow often continued between wild and domestic populations (Marshall et al. 2014).

Animals provide food including meat, milk, and blood and raw materials such as dung, hides, or wool and can also be used for transport and traction. Pastoral families generally employ

herding animals with diverse feeding strategies and uses. Pastoral herd sizes range from a few animals to many thousands depending on factors such as wealth, access to labor and land, climate, and disease, as well as political conditions. Herders move animals to grazing, water, and salt, guard them from predators and rustlers, and monitor their health. Settlements are sited in locations well suited for the needs of domestic stock and revisited over time. Landscape management and cycles of mobility facilitate access to pasture and water but depend on factors such as seasonality, climate, and local flora, as well as enforcement of institutionalized property rights to pastures. Individuals or whole households move with herds at time scales that range from a few days to seasonal, yearly, decadal, and even centennial intervals, depending on environmental and social factors (Wendrich and Barnard 2008).

Most pastoral societies are characterized by social systems that emphasize rights to diverse terrain, through kin relationships and lineages, clans, or age sets. Families make their own herding decisions, however, and often have considerable autonomy. It has been argued, therefore, that mobility and pastoral subsistence systems lend themselves to the development of complex but relatively egalitarian social systems. However, polygamy is common in pastoral societies in Africa and Asia, and in many regions today, older men wield much of the power. Furthermore, highly stratified pastoral societies have existed in most continents through time. Central Asia is especially well known for ancient pastoral empires (Frachetti 2012), and raiding and warfare have been commonly associated with pastoral societies.

Historical Background

There have been long-term debates in anthropology over the role of mobility in society, domestication, and timing of the development of pastoral societies. One of the big questions has been whether hunter-gatherers domesticated animals or whether pastoral societies developed after settled plant-cultivating communities. In the nineteenth century, it was thought that nomadism preceded settled agricultural villages, but as a result of Darwin's evolutionary research, he and other scholars began to focus on the role of genetic isolation in domestication and to argue that animals were more likely to have been domesticated by settled village-based cultivators than mobile foragers. Despite the long-term success and resilience of pastoralism, Western popular culture retains biases against mobile herding ways of life, which can be traced to the difficulty that ancient states faced in controlling mobile peoples, nineteenth-century cultural evolutionism, and historical notions of mobile hunter-gatherers or pastoralists as "primitive." Current anthropological perspectives strongly refute this argument and see the sustainability of pastoral ways of life as one of the long-term success stories of the ancient and modern worlds.

In a different historical twist, scholars studying early cities in Mesopotamia argued that pastoralism developed relatively late as a specialized economic system in response to the establishment of settled urban communities, irrigation systems, and exchange networks in the region. It was proposed that pastoral mobility developed as farmers occupied the best soils and relegated pastoralists to the margins of agricultural areas (Lees and Bates 1974). In the Zagros, however, there has always been an argument for early independent development of pastoral systems (Abdi 2003). The nature of pastoral subsistence has also been much discussed. There are ongoing debates regarding the Secondary Products Revolution or the idea that people's use of animals for milk, hair, and traction was not part of the initial motivation for domestication but led, instead, to the elaboration of herding systems and the spread of pastoralists into Europe (Sherratt 1983). There are also discussions regarding independent incidences of animal domestication and development of pastoral ways of life vis-à-vis demic diffusion from discrete points of origin.

Key Issues/Current Debates

Identifying Domestication

Archaeological research on animal domestication relies on information from animal bones discarded

at archaeological sites and contextual analyses of faunal remains, spatial organization, architecture, and artifacts found on sites. Size decrease has long been the most widely used marker of animal domestication, but it has become increasingly clear that there is a significant time lag after management before size changes are manifested (Marshall and Weissbrod 2011; Zeder 2011). More sensitive indicators include the change in species frequencies, animal age and sex profiles, and pathologies indicating animal use or penning, as well as distribution of animals outside their wild range. Lenses of animal dung resulting from corralling or organic residues indicating milking are also increasingly used to identify early phases of domestication (Outram et al. 2009; Dunne et al. 2012). Genetic studies of extant species and ancient bones are playing a major role in helping to codify the phylogenetic relationships of purported ancestors and domesticates as well as helping to ascertain the location, timing, and number of domestication processes involved.

Domestication and Pastoralism: Regional Variability

The histories of domestication reviewed here and incorporation of sheep, goat, and taurine cattle into pastoral societies around the world provide important insights into the development of diverse pastoral trajectories and their relationships with domestication processes.

The Near East

Sheep and Goats Archaeological and genetic data suggest that sheep and goats were domesticated multiple times by hunter-gatherers living in settled village communities in the higher-elevation headwaters of the Tigris and Euphrates rivers (Zeder 2011). The wild bezoar (*Capra aegagrus*) was the earliest of the herd animals to be domesticated. Goat herds were managed 11,000–10,000 years ago during drier conditions. By 9500 years they were herded at lower elevations outside of their wild range. Genetic data also document at least six maternal lineages of domestic goats and suggest that herders moved them around the Fertile Crescent. Attempts to manage wild herds of Asiatic mouflon (*Ovis orientalis*) also occurred 11,000 years ago. Culling of young male sheep suggests herd management and domestication in Eastern Anatolia and the northwestern Zagros 10,300–9500 years ago.

Herders relied for a long period on a combination of free-living, managed, and fully domesticated sheep and goats. As a result of long-term gene flow among these populations and variable levels of animal management and herding success, domestication was slow and erratic. Scholars have argued that pastoralism developed out of specialized hunting in mountainous regions (Abdi 2003). However, most excavations have explored settled village sites. The extent to which sheep or goat herding was seasonally specialized or undertaken by pastoral subgroups has not been fully examined. This may be remedied by new isotopic approaches to detecting mobility. The high mountains of Iran and Iraq remain relatively little explored from a pastoral perspective, and smaller open sites that might have been created by early pastoralists have not been systematically investigated. The earliest well-documented evidence for nomadic pastoralism in the Zagros Mountains dates to 9000–4000 BP.

Cattle Domestication of taurine cattle (*Bos taurus*) added a key third animal species to the caprine duo relied on by early herders. Aurochs (*Bos primigenius*) are now extinct but were domesticated 10,500–10,000 years ago by settled farmers in the middle Euphrates and high Tigris valleys of the Near East (Zeder 2011). Unlike caprines, taurine cattle were domesticated only once. Recent genetic research suggests that relatively few female cattle were ever domesticated and that people from just a few villages might have been involved (Bollongino et al. 2012). Cattle herding spread into western Turkey and southeastern Europe. Lipid residues in ceramic pots date as early as 9000–6000 years ago, and the genetics of human lactase persistence suggest that milk had an important impact on survival (Gallego Romero et al. 2012).

Development and Spread A mosaic of farming, hunter-gatherer, and pastoral communities lived in the Levant during the PPNB. Pastoral nomadism, it is argued, originated in the Syrian Desert and diffused south (Arikan 2012). In the Negev herders also hunted. In a different pattern, pastoralists living in the increasingly arid environment of Chalcolithic Jordan adopted extensive nomadic pastoral strategies with seasonal cultivation. Land use models suggest this was the most sustainable way to minimize impacts and increase biodiversity in this low-rainfall area.

To the west, domesticated cattle, sheep, and goats and annual crops were progressively incorporated into the European Neolithic beginning 8000 years ago. Mixed farming, herding, and milking are strongly associated with demic diffusion. Specialized pastoralism such as that practiced in the Alps and other mountainous regions of Central Europe probably began as recently as 4000 years ago during the Bronze Age. The specialized management and domestication of reindeer occurred approximately 2000 years ago and independently in northern Scandinavia and central northern Russia.

South Asia

Cattle, Goats, and Sheep In South Asia there is a different trajectory toward pastoralism than in Western Asia, with domestication of wild South Asian cattle (*Bos namadicus*) in the Indo-Iranian borderlands (Meadow 1996). Just as in Western Asia, little is known about smaller sites, and the bulk of the evidence comes from settled villages. Genetic data suggest that humped zebu cattle (*Bos indicus*) were domesticated in the Indus and perhaps northern India. During the eighth millennium BCE, farmers in Baluchistan cultivated wheat and barley, kept goats, and hunted wild cattle and sheep (Meadow 1996; Fuller 2006). Cattle domestication is documented 7000 years ago by age profiles and size decreases indicative of management. Herders subsequently spread zebu cattle west across the Iranian plateau. In South India, ash-mound sites document the development of specialized pastoralism between 6000 and 4500 years ago and possibly preceding cultivation in the region. Four thousand years ago, pastoral systems of the Indian subcontinent incorporated transport animals from other regions including donkeys, horses, and Bactrian camels to create resilient pastoral systems in arid portions of South Asia. Lactase persistence in parts of South Asia attests to the significance of the history of milk-drinking among herding populations (Gallego Romero et al. 2012).

Central Asia

Horses, Bactrian camels, and yaks were domesticated in Central Asia, and these transport and multipurpose animals provided the basis for pastoral systems variously adapted to steppes, deserts, mountains, and high-altitude plateau regions from the Black Sea to China.

Horses Domestication of horses influenced the development of pastoral systems of the Central Asian Bronze Age and transformed scales of mobility and flows of information across Central Asia. Evidence from settlements in northern Kazakhstan, especially the site of Botai, suggests that settled hunters used domestic horses 5500 years ago to hunt wild horses (*Equus ferus*). Geoarchaeological evidence of corals, bit wear on horse teeth, milk residues, and size decrease demonstrate domestication (Outram et al. 2009). Initial domestication likely took place elsewhere. Genetic data document multiple maternal horse lineages across Central Asia and suggest gene flow over the long term among wild and domestic populations.

The introduction of domesticates from Western Asia enhanced horse-based pastoralism and triggered later Middle Bronze Age (4500–3500 years ago) forms of nomadic pastoralism that incorporated Western Asian cattle and sheep. Horses were used for meat, skins, milk, and transport, associated with the sun god, and used in ritual sacrifice. A recent hypothesis suggests that pastoralism and herding animals could have spread from west to east through the Inner Asian mountain corridor instead of the steppes (Frachetti 2012). Nomadic pastoralists in Mongolia, 2500 years ago, relied on diverse subsistence strategies including horses, domestic caprines, cattle, hunting, and cultivation

(Wright et al. 2009). Furthermore, organized landscapes reflect long-term revisiting of sites best suited for pastoral settlement. In areas such as Northern Mongolia, there is also evidence for trade, hierarchy, and semipermanent pastoral habitation.

Bactrian Camels The domestication of two-humped Bactrian camels transformed people's ability to live in the cold deserts of Central Asia and opened up desert trade routes. Bactrian camels are thought to have been first domesticated between China and Mongolia. There is little osteological information, however, on the social context, place, and timing of domestication. Ancient DNA from Iron Age sites and the lack of geographic variability among modern domestic camels from China and Mongolia have led scholars to suggest a single center of domestication. Genetic research has demonstrated, though, that endangered wild Bactrian camel populations are not the ancestor of the domestic two-humped camel. On the basis of early distribution outside their wild range, archaeologists suggest that Bactrian camels were domesticated 6000–4000 years ago (Peters and von den Driesch 1997). After domestication the range of domestic Bactrians expanded west to Turkmenistan where clay figures of Bactrian camels pulling carts date to the early third millennium BCE (Meadow 1996). In South Asia two-humped Bactrian camels appear in the late third millennium BC, probably through northern Afghanistan, whereas in Northwest China, camel bones date to about 3000 years ago.

Yaks Yaks were domesticated by hunters of the Tibetan borderlands (Rhode et al. 2007). Genetic studies document the presence of two maternal lineages of domestic yaks suggesting two domestication events or gene flow. Yak dung has played an important role as fuel on the Tibetan plateau, and it has been argued that this may have been a motivating factor in domestication. Yaks were used for milk, hair, and meat and as pack animals. They are also spiritually important in the region. Yak-based pastoralism has played an important role in the settlement of the high-altitude regions of Central Asia and the development of trade and interconnections among valleys, plateaus, and mountain ranges of the region. Yaks were adopted by both herders and mixed farmers from the Himalayas to the Kunlun Mountains and through the Gobi to Mongolia and Siberia.

Arabian Peninsula

Domestication of dromedaries allowed people to survive over the long term as pastoralists and traders in the arid deserts of the Arabian Peninsula and Africa. Recent research indicates that the extinct giant camel (*Camelus thomasi*) was the wild ancestor of the dromedary or Arabian camel. Large numbers of camel hunting sites on the eastern coast of the Arabian Peninsula suggest that dromedaries were domesticated there 6000–4000 years ago (von den Driesch and Obermaier 2007). Pastoralists of this region came to rely heavily on camels for milk and as a result have high frequencies of lactase persistence today. With domestication the ancient range of the dromedary expanded along trade routes to Iran and South Asia. Camels date to 2000 years ago in Africa and became an increasingly important part of subsistence and trade as deserts expanded. Pastoral societies of the Horn have been shaped by their reliance on camels for milk, meat, and blood. Saharan camel trains are depicted in rock art and associated with the development of specialized gold and salt trade routes. In the Arabian Peninsula and Sahara, camel-based pastoral groups played a role in the development of complex polities.

Africa

Pastoralism was the earliest form of food production on the continent and allowed Africans to cope with the mid-Holocene expansion of the Sahara (Gifford-Gonzalez and Hanotte 2011). Microsatellite and paternal genetic data, and the timing of the appearance of cattle before sheep and goats, suggest that settled hunter-gatherers may have domesticated African cattle in the eastern Sahara (Marshall and Weissbrod 2011). It is also likely that incoming taurine cattle from Asia were interbred with local wild cattle. A thousand years later, Near Eastern domestic sheep and goats were

integrated into mobile herding, hunting, and gathering systems that spread across Saharan grasslands. These herders also domesticated a desert-adapted animal, the African wild ass (*Equus africanus*). Genetic data documents high diversity in African donkeys and two maternal haplogroups suggesting two African populations played a role in domestication. Cattle, donkeys, sheep, and goat complement each other, increasing resilience by providing herders with animals that have dissimilar life cycles, feeding habits, and disease susceptibilities. Lipid residues in ancient pots from Southern Libya demonstrate that herders were relying on cattle for milk as they moved west from the central Sahara by 7000 years ago. Milk fats from a range of plants also indicate a seasonal pastoral system in the Acacus, with herders moving between the mountains and the plains (Dunne et al. 2012). As the African humid phase ended, hyperarid conditions developed in the Sahara 6000 years ago. Herders moved more frequently and relied more on sheep and goats. Monumental cattle burials appear at this time, and abundant pastoral rock art testifies to ritualization of cattle.

Pastoralists ultimately abandoned the Sahara, migrating to the Nile Valley and Sahel. Herders with generalized domestic and wild subsistence bases also moved as far south as East Africa 5000 years ago. In Southwest Kenya, specialized pastoralists relied on domestic stock without hunting abundant large mammals approximately 3500 years ago. It has been argued that this subsistence choice reflected pastoral identity as people who eat cattle, rather than wild meat (Marshall and Weissbrod 2011). Pearl millet was domesticated 4000 years ago in West Africa by pastoralists who settled in the Sahel. After this time, seasonal cultivation became part of the repertoire of many pastoralists. Disease threats affected the spread of pastoralism in Africa, but trypanosomiasis-resistant cattle breeds attest to the adaptation of African cattle to the wetter tsetse belt of West Africa (Gifford-Gonzalez and Hanotte 2011).

South America

Pastoralism developed in the Andes between 6000 and 4000 years ago with the domestication of llamas and alpacas and the development of distinctive pastoralist societies (Mengoni-Goñalons 2008). Genetic research has demonstrated that the guanaco (*Lama guanicoe*) is the wild ancestor of the llama and the vicuña (*Vicugna vicugna*) the wild ancestor of the alpaca. Considerable hybridization has also been documented (Wheeler et al. 2006). Recent research suggests that camelid pastoralism developed to buffer against the climatic and environmental unpredictability that characterized the Andean highlands throughout the Holocene. Domestication of Andean camelids now appears a more diverse and dynamic process than previously thought. Growing evidence from southern Peru, Northern Chile, northwestern Argentina, and western Bolivia suggests multiple simultaneous instances of domestication outside the Peruvian central highlands. Long archaeological sequences from widespread highland sites document specialized hunting of wild camelids between 10,000 and 6000 years ago, followed by a period of intensive management and the eventual formation of distinctive herding communities 5000–3500 years ago. There is evidence for long-term herding in the highlands and the introduction of domestic camelids to the coastal, eastern, and northern Andes as early as 4500 years ago.

In the Andes, pastoralism was complemented by other subsistence strategies as it developed, and these varied with environmental and social settings. In the Bolivian central Altiplano, Wankarani pastoralists employed camelids in a diverse subsistence strategy that included fishing, cultivating, and use of a range of wild resources. Domestication of llama's secured access to meat, transport, and dung for fuel, but the motivation behind herding alpacas was to produce fine wool with which to make textiles. Pastoralist specialization in some areas resulted in herders depending on specialized wool-producing breeds. Highland farming societies also incorporated domesticated camelids from early on to complement agricultural production. Meat-, wool-, and pack-based pastoralism allowed denser settlement in high-altitude regions of the Andes and has proven a resilient way of life.

Emerging Patterns

New data and increasing research in Central Asia, Africa, and South America are providing fresh perspectives on domestication and contexts for the development of pastoralism. Two common assertions regarding the timing of the appearance of pastoral systems are that plants were domesticated before animals and that pastoralism developed late and out of settled villages and towns of early states. Thinking about these processes was initially framed in Southwest Asian contexts. Sheep and goat were the earliest herd animals to be domesticated worldwide, and recent syntheses show that they were domesticated in the Fertile Crescent at about the same time as the earliest plants. Similarly, in South America, hunter-gatherers domesticated camelids at the same time as many Andean cultigens. In Africa, however, domestication of donkeys and incorporation of introduced animals and the development of mobile early pastoral societies preceded domestication of African plants by several thousand years. In Central Asia pastoral systems are variable, but there is no indication that cultivation occurred as early as herding. In Baluchistan, however, there are complex patterns of cultivation of introduced wheat and barley prior to the domestication of zebu cattle. However, in South India, early cattle pastoralism preceded cultivation. Current data suggest that domestication of South Asian plants occurred after the earliest pastoralism and in regions where pastoralism was never common.

Answers to the related question of whether pastoralism developed late and out of the settled villages and towns of early states are straightforward in some regions and less so in others. There are strong indications that domestication resulted from specialized hunting and widespread modification of the environment starting 12,000 years ago (Zeder 2011). But whether goats and sheep were also incorporated into residentially or seasonally mobile pastoral systems in the Fertile Crescent or whether they were largely integrated into systems of village-based agriculture is unclear. The timing of the earliest pastoralism in Southwest Asia is, therefore, unknown. By contrast, in Africa and the Andes, hunter-gatherers or early herders domesticated a range of animals and pastoral sociopolitical systems developed well prior to the appearance of settled polities. Similarly, the first evidence for reliance on domestic horses is among hunter-gatherers. It is possible, however, that horses were domesticated by people further to the west who kept cattle and cultivated crops. It is clear, however, that the development of pastoralism in Central Asia stimulated the development of complex nomadic societies and states, rather than the other way around. Settled towns and polities played no role in the development of horse pastoralism in Central Asia. Simple statements about the relative timing and spread of farming and pastoral systems obscure complex climatic shifts and subsistence histories and sociopolitical contacts that made one system or the other more likely to flourish at any given time. But it is clear that plants were not domesticated earlier than animals as a general rule and that in many cases pastoralism developed before ancient states.

Research carried out during the last 20 years shows that animals were domesticated and pastoralism was developed in widely dispersed areas of Eurasia, Africa, and the Andes. However, there is still tension between the ideas of independent origins and diffusion, and with the exception of relations between Southwest Asia and Western Europe, relatively little is known about the nature and timing of regional contacts. Recent research suggests passage of people, animals, and ideas across Iran from the Near East to South Asia. Similarly, it has been argued that horse-based pastoralism spread through long-distance movements from west to east across the Central Asian steppe and the Inner Asian mountain corridor. Current discussions of Central Asia focus less on migrations as mechanisms for social change and more on relatively small-scale pastoral movements, repeated revisiting of the same locales, and extensive interactions among mobile pastoralists during seasonal rounds (Frachetti 2012).

The question of whether herders started to milk animals early or whether milking and use of animals for hair, and traction, was part of later pastoral development and spread is another issue that has been much discussed (Sherratt 1983). Recent

research demonstrates, though, that in Turkey, milk residues on pots date to as early as 9000 years ago (Dunne et al. 2012). Pastoralists moving into southeastern Europe 8000 years ago also relied on milk (Gallego Romero et al. 2012). The same is true of the earliest cattle pastoralists moving west across the central Sahara 7000 years ago. Horses were also milked in the earliest phases of domestication by herder-hunters in northern Kazakhstan about 6000–4500 years ago (Outram et al. 2009). As a result, scholars now suggest that secondary products may have been part of the early motivation for people to manage herd animals. Drinking milk conferred such a survival advantage on pastoralists that different genetic pathways for lactase persistence developed in Europe and Africa. Lactase persistence is a pastoral legacy and geographically concentrated at high frequencies today in northwestern Europe, parts of Africa, Southwest Asia, the Arabian Peninsula, and Mongolia.

Future Directions

Well-known pastoral regions of the world such as the Andes, Africa, and Central Asia have seen far less research than areas that have long been under intensive cultivation such as Western Asia, Western Europe, Eastern China, or North America. Ongoing research is addressing these imbalances. Furthermore, pastoral sites are by definition ephemeral, and there is a need for more highly trained pastoral archaeologists. Global geopolitics as well as applied issues such as the need for sustainable food production and mobile responses to climate change are, however, expanding the scope and relevance of pastoral research. New methods of detection of pastoral sites and early stages of animal management such as micromorphology and soil chemistry, as well as breakthroughs in the study of isotopes and ancient and modern biomolecules, are also making it possible to conduct much more systematic and fine-grained archaeological research on domestication and mobile pastoral societies.

Future research is needed on regional variability in pathways to pastoralism at a range of scales. There is evidence for different pathways to pastoralism in South America, Africa, and Central Asia, for example. There is much less information, however, on smaller-scale variability in patterns of camelid domestication or breed development within regions – such as the Peruvian or Bolivian Andes. Similarly, little is known about differences in the way that Bactrian camels and dromedaries were domesticated. It has also been suggested that there are resemblances between the development of cattle-based pastoralism and late cultivation of crops by early herders in northeast Africa and South India, but multisited research projects have not attempted systematic data collection and comparison between continents.

Ethnohistoric research in Africa and the archaeology of Cyprus also make it clear that small groups of people and their animals suffered periodic reverses with pastoralists becoming hunter-gatherers, animals becoming feral, or local populations of cattle or other livestock being decimated. Research on these and other small-scale processes that are critical to domestication and breed formation will be greatly enhanced by long-term regional archaeological studies that integrate fine-grained research on zooarchaeology, paleogenomics, geoarchaeology, paleoecology, and human behavior.

Animal Exploitation on Neolithic Sites in Central Germany

Introduction

More than ten millennia ago, people invented agricultural practices and domesticated various species of plants and animals in the Near East, as well as in other regions of the world. This Neolithic Revolution, as it was called by V. Gordon

Childe, involved mankind changing from a predation to a production economy. Observed from a technical point of view, this phenomenon caused another, called by A. Sherratt "Secondary Products Revolution." The causes of this transition were of environmental, demographical, and/or ideological nature. The time of onset varies for new activities like animal traction, milk, and wool production. Later during the Neolithization Process, in the seventh millennium BC, Near Eastern settlers brought their know-how and their agropastoral equipment into Europe. This primary Neolithization came to an end during the fourth millennium BC, a threshold epoch in which also climate change occurred and fundamental transformations led to the emergence of less egalitarian societies in Central Europe. Revealing in which way Neolithic animals were exploited in a particular time and place contributes to this broad debate about timing and diffusion of the so-called secondary products and their consequences. This is the aim of our study of Neolithic sites in the Elbe-Saale region.

Definition

The study of animal bones from archaeological sites provides information about man–animal relationships. All these relations form a pastoral subsystem, which depends on natural constraints and varies according to cultural choices. This technical subsystem based on animal resources is illustrated here by insisting on the animal's status: alive or dead (Fig. 1). Animal behavior, maintenance, and recycling are also incorporated. Transforming a natural element into a final product is made by a succession of operations, starting with acquisition and maintenance. Then, depending on their needs, men choose either to keep the animal alive to obtain lifetime products or to kill it for final products. These raw materials can be used or transformed into more sophisticated products, like cheese or leather. A particular case exists: the inhumation of an animal in a burial or accompanying a man. Related to its use, this animal is granted a preferential status compared to other animals. The technical subsystem based on animal resources is in direct interaction with other technical subsystems, and this technical system as a whole is linked to social, symbolic, physiological, etc. systems, which together inform us about the life of past society.

Key Issues/Current Debates/Future Directions/Examples

Before exposing the major results of animal exploitation on Neolithic sites in Central Germany, it is useful to present the geographical and chronocultural context, to overview the key issues under debate and to point out the limits of the documentation.

An Environment Conductive to Agropastoral Practices for More than 3000 Years

The Elbe-Saale region is a territory of about 40,000 km^2 covering the *Länder* Saxe-Anhalt, Saxe, and Thuringe. The landscape is characterized by the last glacial period and several watercourses pass through it, like the Elbe and Saale. Vegetation is varied because different soil types exist, as, for example, the fertile Chernozem which is one of the most profitable European lands. The subcontinental climate, with hot summers, harsh winters, and low annual precipitations, imposes a husbandry adapted to these conditions. Around 3700 BC, the passage from Atlantic to Subboreal induced a cooler and dryer climate and important forest clearances made by Neolithic settlers let to the elm and linden decline.

This region was densely inhabited between 5500 and 2200 BC. Based on established chronologies (Lüning 1996; Müller et al. 2012), Fig. 2 presents the sequence of cultural groups observed in the Elbe-Saale region (MES). Since the Early Neolithic, people from the Linear Pottery Culture settled there. During the Middle Neolithic appeared the Stroked Pottery Culture, Rössen and Gatersleben, the last cultural group continuing in the Younger Neolithic. During this period occurred also the Jordansmühl. At the end of the Younger Neolithic, a local group of the Michelsberg Culture existed: the Hutberg, which

Animal Exploitation on Neolithic Sites in Central Germany, Fig. 1 Technical subsystem based on animal resources (Modified after Tresset 1996: Fig. 3; Vigne 1998: Fig. 1) integrating behavior, maintenance, and recycling

was partly contemporaneous with the Baalberge. From the Late Neolithic on, various cultural groups cohabited in this area, some occupied the same territory (Salzmünde, Walternienburg, Bernburg, Globular Amphora Culture – KAK), others avoided each other (Salzmünde and Tiefstich). These groups, except the KAK, were regional groups of the large Funnel Beaker Culture complex (TRB). The Final Neolithic is marked by the Schönfeld, the Corded Ware, and the Bell Beaker Cultures.

A Special Framework to Understand Social Change and Man–Animal Relationships

The Elbe-Saale region is an archaeo(zoo)logical well-documented area. In the last decades, the fauna from Early Neolithic sites was analyzed in detail (Müller 1964a; Döhle 1994) and several faunal studies exist for the Younger and Late Neolithic (consult the inventories in Döhle 1997; Höltkemeier 2016: 258). The first archaeozoological syntheses are devoted to the state of research (Döhle 1997; Benecke 2006)

Animal Exploitation on Neolithic Sites in Central Germany, Fig. 2 Chronology for the Elbe-Saale region (MES) between 5500 and 2200 BC. Some cultural groups belong to the Funnel Beaker Culture complex (TRB)

and some supra-regional syntheses are concerned with specific issues, such as horse domestication (Uerpmann 1990; Benecke 2006). Recently, the fauna of two eponymous enclosures, Wallendorf "Hutberg" and Salzmünde "Schiepzig," were examined and placed in their regional context (Höltkemeier 2016). Moreover, DNA analyses revealed that the mare from Salzmünde is a domestic horse (Benecke et al. 2013).

Key issues currently debated are rather classical, as the characterization of subsistence economy, which can be based on hunting, gathering, or farming. More specifically, it is pointed out which animal species were used and why – for meat/milk/hair/draught or mixed exploitation. Not only used for economic purposes, animals can also have a particular social status and this can be reflected in the symbolic system. Other research topics are animal size and health, which provide information about the agropastoral practices and their conditions. An old theme still relevant is the differentiation of wild and domestic animals. Thanks to recent increases in data, these debates can be refined and research can be undertaken in the study area on specific practices, such as castration or traction, and their evolution during the Neolithic.

The Documentation and Its Limits

Fifteen archaeozoological studies for Neolithic settlements are considered and almost 40,000 identified bones are used for the analysis (Fig. 3). Sites with an uncertain chronological attribution are excluded from this inventory. The sites are mainly located in Saxony-Anhalt, in or near the Saale valley. Data disparities exist between them and also between chronological periods. Indeed, Krautheim is the site where most of the bones were discovered and the Late Neolithic is the best documented period in the current state of research. The data published by H.-H. Müller (1964a) are chronologically differentiated, but the faunal remains of each site are insufficient for comparisons between sites. Therefore, we have only an overview for the Early and Middle Neolithic sites. Eight cultural groups are represented: Linear and Stroked Pottery, Hutberg, Tiefstich, Salzmünde, Bernburg, Schönfeld, and Corded Ware. Unfortunately, only few data for the Younger Neolithic exist, resulting in a gap in data between Rössen and Jordansmühl. Faunal spectra, logarithm size index (LSI), gender distinction, paleopathology, age at death estimations based on teeth eruption and wear are used to compare the data. The detail of the applied methodology can be consulted in a PhD thesis chapter dedicated to this topic (Höltkemeier 2016: 70–116).

Animal Supply and Evolution of Subsistence Practices

In the Neolithic, animal food economy is based in the study area on farming and proportion of domestic animals is over 90% (Fig. 3). On the majority of sites, cattle are with over 50% the best represented species. At Niedergörne, fishing and mussel gathering are so significant that one might suggest that the site is specialized in these activities. At Eilsleben and Magdeburg Neue Neustadt, breeding is below the threshold of 90%. More specifically, at Eilsleben, Halle Dölauer Heide, and Quenstedt, cattle represent less than 50%. Sheep are much more prevalent than goats for all sites and this could reflect a special exploitation mode. In general, pigs are less important than sheep and goats. While caprines become economically less important at the end of the period, the proportion of pigs remains relatively stable.

Evolution of Size and Morphological Variability for Cattle, Sheep, and Pig

To apprehend the consequences of human intervention on animals and their size evolution, histograms and box plots based on LSI values are established. The values are obtained by species with osteometrical data from archaeological sites compared to measurements of a standard individual and are clustered by chronological period. The box plots are detailed by age class and anatomical part (limb, bone). The first version can reveal size changes during growth; the second version can indicate differences in skeletal proportions between the ancient population and the standard individual.

Cattle have the smallest size during the Younger Neolithic, with a LSI mean of −0.11 (Fig. 4). Between the Early and Middle Neolithic, their size increases slightly because the LSI mean

Animal Exploitation on Neolithic Sites in Central Germany, Fig. 3 Studied sites of the Elbe-Saale region and proportions of their animal species

changes from −0.05 to −0.04. This could be related to a change of livestock compositions, with a higher number of bulls or even oxen, or could be due to an introduction of freshly domesticated individuals. In the Late Neolithic, few individuals reach the proportions of a female aurochs and those concerned are oxen. The data for the Final Neolithic are scarce; all of them are inferior to the standard individual. By comparing the data of cattle with them of Neolithic aurochs from the Elbe-Saale region, it appears that the LSI values around zero overlap, but that generally the aurochs is in terms of proportions higher than cattle, and this is value since the Early Neolithic. Moreover, changes are perceptible during growth. At the first age class (individuals aged less than 1 year), cattle grow up a little slower. Generally, bovine growth is rather homogenous

Animal Exploitation on Neolithic Sites in Central Germany, Fig. 4 Logarithm size index (LSI) distribution for cattle (*Bos taurus*) by chronological period and for Neolithic aurochs (*Bos primigenius*) from the studied sites. Indication of mean (black arrow) and median (gray arrow)

during the Early and Late Neolithic. During the Younger Neolithic, some low values exist for the age class 2–3 years. This could be a more pronounced proportional change caused by particular agropastoral practices.

Sheep are smaller in the Early Neolithic than in the Late Neolithic, because the LSI mean increases from −0.09 to −0.05 (Fig. 5). At the end of the period, large sheep are more abundant – the question is if this is due to an increase of males

Animal Exploitation on Neolithic Sites in Central Germany, Fig. 5 Logarithm size index (LSI) distribution for sheep (*Ovis aries*) and pig (*Sus domesticus*) by chronological period and for Neolithic goat (*Capra hircus*) and wild boar (*Sus scrofa*) from the studied sites. Indication of mean (black arrow) and median (gray arrow)

within the herds or because of an introduction of new, larger sheep, which could be wool breeds? Even if the size of goats is overlapping with that one of sheep from the studied area, confusion between these two species can be excluded because the LSI values are based on specifically identified bones.

The data are sufficient to illustrate the morphological variability of pigs for the Early and Late Neolithic (Fig. 5). Their mean size increases from −0.10 to −0.07 and Linear Pottery pigs aged between 1 and 2 years grow up a little faster. Compared to a male boar, the hindlimbs are slightly larger than the forelimbs, which could be related to a selection of individuals with well-developed posteriors. The pigs are proportionally similar but are taller than Neolithic local wild boars. Thus, these data do not argue in favor of hybridization between pigs and local wild boars.

The Herd Management Reveal a Varied Animal Exploitation

To find out how Neolithic settlers handle their livestock in this region and to know for what purposes the different species are raised, slaughter ages, gender distinction, and animal health were analyzed.

It turns out that animal husbandry practices are relatively well developed. The castration of bulls is possible for the Younger Neolithic, at Wallendorf, and is certain for several Late Neolithic sites (Fig. 6). This activity is even proposed for Early Neolithic cattle, as, for example, at Hohlstedt (Müller 1964a: 16–17). Bulls are castrated to provide a large supply of tender meat, as at Quenstedt, and to get docile individuals for traction, as at Salzmünde. On this enclosure, cattle are primarily raised for their meat and their draught power and secondarily for their milk. Slaughtering peaks for calves aged less than 1 year are observed for one Younger Neolithic site and some Late Neolithic sites. These peaks reflect the practice of post-lactation, which means the slaughtering of calves at the time of their weaning (Tresset 1996: 80–83). Milk exploitation is also demonstrated by a high slaughtering of cows aged between 4 and 6 years, whose milk production decreases. This is well illustrated at Krautheim. The herd composition is variable with one bull for one cow (Quenstedt) to one bull for three cows (Wallendorf, Salzmünde). At Krautheim, the sex ratio is almost in equilibrium if the oxen are considered but stands at one male for ten females if the castrated individuals are excluded.

At least during the Bernburg period, rams are castrated for meat and/or textile exploitation, as at the enclosures of Krautheim, Quenstedt, and Großobringen (Fig. 6). The exploitation can be "type A" or "B" for milk or meat, with a preference for quality in the first case and for quantity in the second case. For example, a "type B milk exploitation" is coupled to a "type A meat exploitation" at Salzmünde and Krautheim. Moreover, sheep are raised for their hair at Salzmünde and Großobringen. The herd is composed of three males for one female at Salzmünde and by one ram for five eves at Großobringen.

Cattle and sheep are raised for mixed exploitation, although some sites are apparently more specialized, especially during the Late Neolithic. For example, meat exploitation predominates at Quenstedt, Krautheim is more involved in dairy products, and at Salzmünde, cattle are used for traction and sheep for textiles.

Pigs are the choice suppliers of meat, because their gross return on slaughter is higher than cattle or caprines. Yet this species seems to be less important on most sites, supporting the hypothesis that the need for other products is essential in this region. Providing tender meat is the main objective of pig breeding, and this is valuable since the Early Neolithic. For example, at Eilsleben, half of the herd is slaughtered under the age of one year (Döhle 1994: 72). This is comparable with Wallendorf and Quenstedt, where the herds are sharply reduced before the sexual maturity of females (Fig. 7). On other Late Neolithic sites, some older sows are kept for reproduction. Gender distribution is balanced on almost all sites. Occasionally, males can even be more abundant than females, as during the Younger Neolithic.

Skeletal alterations on bovine bones are known since the Early Neolithic. Indeed, an acetabulum with a polished surface (in German "*Schliffusur*") in the pubis part comes from the enclosure Eilsleben (Döhle 1994: 53) and enlarged bones are also mentioned (Müller 1964a). For the

Animal Exploitation on Neolithic Sites in Central Germany, Fig. 6 Slaughter profiles (at left) and survival curves (at right) based on teeth (Nd) or minimum number of individual animals (MNI) for cattle (*Bos taurus*) and caprines (*Ovis aries/Capra hircus*)

Animal Exploitation on Neolithic Sites in Central Germany, Fig. 7 Slaughter profiles (at left) and survival curves (at right) based on teeth (Nd) or minimum number of individual animals (MNI) for pigs (*Sus domesticus*)

Younger Neolithic, cattle phalanxes from Wallendorf are enlarged and have exostoses (Fig. 8). However, these anomalies become really frequent during the Late Neolithic, because many cases exist on a number of sites. For example, 28 bones from Salzmünde are affected by pathological deformations reflecting skeletal stress. Concerned are the scapula, coxal, femur, metapodials, and phalanxes. Figure 8 shows among other bones a femoral head with a little *Schliffusur*. At Peißen, a metatarsal condyle is enlarged (Becker 1999), at Großobringen, eight Phalanx I have exostoses (Barthel 1985), and at Quenstedt, six acetabula are affected by a coxarthrosis (Müller 1985). Calculating the pathological index is a rather recent method and could only be applied for Wallendorf and Salzmünde; their respective mean values are 0.23 and 0.36 (Höltkemeier 2016). Otherwise, the three main domestic species (cattle, sheep, pigs) show some dental anomalies, and bone fractures are observed since the Early Neolithic for cattle and caprines and since the Late Neolithic for cattle, caprines, pigs, and dogs.

Animals Used in the Symbolic Sphere

More than a mere supplier of raw materials, an animal can be perceived differently by men. It is

Animal Exploitation on Neolithic Sites in Central Germany, Fig. 8 Cattle bones from Wallendorf "Hutberg" (at left) and Salzmünde "Schiepzig" (at right) with anomalies due to skeletal stress (Photo: S. Höltkemeier)

not only part of the technical system but also of the symbolic system and both are linked (Fig. 1). The symbolic system can inform us about mental representations which humans had for animals and about the social value that they gave to them.

In the Elbe-Saale region, a new activity has particularly affected the Neolithic people – animal traction. This is reflected by cattle depositions, which occur since the Salzmünde cultural group. Often, these are buried pairs of adult cattle, placed side by side or face to face, and which can be cows, bulls, or oxen. In some cases, they are associated with human graves. In the current state of research, this practice is most recurrent in the study area during the Amphora Globular Culture, but it persists during the Corded Ware Culture and the Schönfeld cultural group. Other more classical depositions exist also, like animal parts, especially animal skulls. Cattle are the most common species, but there are also dog, sheep, pig, horse, and some wild animals, such as red deer and fox. Depositions of animal parts are often intentional deposits in a funerary context, fire and destruction can play a role in funerary rites, as at Salzmünde (Höltkemeier 2016: 299–302).

Future Directions

In order to contribute to the wide-ranging debate about dating and diffusion of new agropastoral activities, it is fundamental to adopt a holistic approach. This is carried out with a fine characterization of the technical subsystem based on animal resources. Using effective methods enables us to understand several aspects of man–animal relationships. Consideration of other archaeological data related to this subject, such as iconographic elements (as harness representations of animals) or artefacts linked to a specific exploitation (such as cheese vessels, yokes) can support the archaeozoological results and replace them in a larger context, in order to apprehend the connections between people and their environment.

The obtained regional synthesis shows aspects of animal exploitation in the Elbe-Saale region and its development through the period between 5500 and 2200 BC. However, the study requires further refinement and extension. Therefore, more archaeozoological data for the poorly documented periods (Younger and Final Neolithic) must be acquired, which implies future excavations. Moreover, it would be interesting to examine the

role of cattle in Neolithic landscape transformation, with interdisciplinary research. Future work with DNA and stable isotopes will be necessary to confirm the presence of sheep wool breeds and milk exploitation on some specialized sites.

A

Animal Paleopathology

Robin Bendrey
School of History, Classics and Archaeology, University of Edinburgh, Edinburgh, UK

Introduction

A relationship is a two-way entity. The different partners within it influence each other to a greater or lesser extent. So it is true for the long history of human-animal relationships (Fig. 1): each has affected the individual lives, and also the historical trajectories of whole populations, of the other. It is these stories that animal paleopathology can elucidate. The domestication of animals, for example, changed the course of development of human society and economy and in doing so affected human health and disease. Bringing animals together in larger, denser herds, in close association with human communities, would have changed the ecology of infectious diseases for both parties.

Definition

Animal paleopathology is the study of health, disease, and injury in past animal populations from the analysis of preserved hard and soft tissues. It is concerned primarily with the bones and teeth routinely recovered from archaeological sites but can also include studies of soft tissues

Animal Paleopathology, Fig. 1 Example of a human-animal relationship: a man travelling by donkey (modern Greece). (Photo: author)

(mummified remains; bog bodies) and articulates with a range of related research areas, such as paleoparasitology, paleodiets, molecular biology, veterinary medicine, and human paleopathology. Through studies of skeletal abnormalities and alterations related to disease and injury, a range of interpretations can be formed and forwarded relating to past economies and societies, environments and living conditions, animal husbandry techniques, and disease ecology.

Key Issues/Current Debates/Future Directions/Examples

The current state of the discipline of animal paleopathology and several of the key issues under debate (in particular those relating to methodology) are perhaps best viewed and understood through a brief retrospective on the discipline.

Methodological Problems and Biases

In considerations of the state of the discipline, parallels are often drawn with its close relative, human paleopathology (O'Connor 2000: 98; Thomas and Mainland 2005). Human paleopathology is a discipline reaching back into the nineteenth century. It is a mature subject, with well-established and consistently applied protocols and methodologies. Animals were included in paleopathological reviews in the earlier twentieth century, but it was only from the 1960s, with the work of such specialists as R.A. Harcourt and D.R. Brothwell, that the foundations of animal paleopathology really began to take off. The publication in 1980 of a general textbook on the subject by Baker and Brothwell (1980) is widely recognized as a seminal moment for animal paleopathology. This volume, a collaborative work between a veterinary pathologist and a zooarchaeologist, reviewed the potentials of the discipline and the abnormalities that might be identifiable within zooarchaeological assemblages. In the subsequent decades, animal paleopathology has developed slowly and rather erratically, and in comparison to human paleopathology, methodologies have unfortunately not been applied consistently to studied material (Thomas and Mainland 2005; Upex and Dobney 2012).

The discipline developed into a situation where common practice was to publish "interesting specimens" (Upex and Dobney 2012). On the one hand, these publications can be useful as

they raise the profile of certain recognizable disorders to the wider zooarchaeological community, hopefully encouraging their future recognition; on the other hand, the absence of proper articulation with their full context, and other forms of archaeological evidence, limits their broader importance. This general approach has been linked with relatively limited publication of prevalence rates (the number of cases of disease or infection in relation to the unit of population in which they occur). It is important to synthesize and compare data to understand geographical and chronological variability. To this end, prevalence rates should be routinely calculated and published. The lack of standardization has led to a situation where studies are not often comparable; even more problematic is the fact that pathology is not always recorded or reported.

This lack of methodological refinement and systematic application has been attributed to several factors (Thomas and Mainland 2005). Most zooarchaeological assemblages consist of disarticulated and fragmented skeletal elements, and complex taphonomic processes (differential destructive processes associated with slaughter, butchery, cooking, consumption, and discard behaviors) further bias the recoverable data (Bartosiewicz 2008). These factors, often resulting in pathological bones being separated from the context of the whole individual, mean that there are often multiple etiologies for a single pathological lesion type. Linked to taphonomy, it is the case that some pathologies are more likely to survive than others.

Full understanding of pathologies is not supported by control studies in modern populations. There are further methodological problems related to the identification, recording, and interpretation of pathologies. One key problem, for instance, is determining what should be considered "normal" (O'Connor 2000: 107). As the premise of paleopathology rests upon identifying, quantifying, and interpreting abnormal alteration from a healthy state, we need to understand the full range of normal variation that might occur. Modern comparative studies of known life history populations will help in the assessment of what is "normal" and what is pathological and will be able to improve knowledge on conditions that remain poorly understood (O'Connor 2000; Thomas and Mainland 2005).

The inconsistent application of paleopathological research may perhaps be viewed in the context of the variability in methodologies applied in zooarchaeological research more generally (due to differing research agendas, project aims, personal research interests, publication space, and financial/time constraints). Pathologies tend to be an infrequent occurrence in zooarchaeological assemblages and may not be prioritized for research. Problems may also stem from a lack of familiarity with veterinary medicine research and also with the archaeological relevance of the diversity of pathological lesions. In many senses the discipline has been a story of unrealized potential to date, and studies have been somewhat sidelined, although they can contribute key information in relation to the human past (discussed below).

The discipline, however, has seen significant advances in the last 20 years or so, in the development and application of methodology, occurring alongside a number of developments promoting animal paleopathological research and publication. Established in 1999, the *Animal Palaeopathology Working Group* of the *International Council for Archaeozoology* was founded to address the problems discussed above, especially the integration of paleopathological data with other forms of evidence; improvement in recording practices and their systematic application; and improvement in the knowledge of the underlying biological processes and consequences of disease and injury. Further, 2011 saw the launch of the *International Journal of Paleopathology*, a journal dedicated to the publication of both human and animal disease.

The Functioning of Economies and Societies

Animals have been, and are, a central part of human existence: they are part of our economies, providing dietary staples and physical work; we form emotional attachments to them; and through our close associations, we share diseases with them. Animal paleopathological research can inform on all of these broad themes.

Until the mechanization of wheeled vehicles, animal power played an essential role in land transport, agricultural production, and warfare. Their use thus had major repercussions on human society and economy with cattle plowing, for example, allowing the intensification of agriculture, and horse riding bringing into human use an animal that revolutionized how people could travel, communicate, and fight each other. Pathological changes occurring in the skeletons of animals used for transport and work can provide evidence of these past uses.

Bone skeletal elements undergo adaptive remodeling in response to increased functional strain – essentially bone deposition is stimulated by extra forces acting on the skeletons (Fig. 1). This can produce joint arthropathies in animals used for work (Fig. 2), although it is the case that such morphological changes also develop as a function of other factors, such as age, sex, body weight, work undertaken, living conditions, and genetic predisposition (Bartosiewicz et al. 1997; O'Connor 2000: 99–101). It is only through the study of collections of modern skeletons with known life history that it will be possible to understand the different influences of the separate factors. Study of such comparative, control populations has contributed to the development of criteria usable to explore the identification of the human use of animals for work in the past, such as the use of cattle for traction (e.g., Bartosiewicz et al. 1997) and the horse for transportation (e.g., Bendrey 2007; Fig. 3). These criteria need to be robustly tested and revisited with reference to new and more diverse control collections to assess their validity, for example, current debates over the reliability of different methods for identifying bitting damage in horses (Bendrey 2007) will hopefully continue as methods are improved and refined.

Again, a further complicating problem with such studies is that as most zooarchaeological material recovered is both disarticulated and fragmentary, it is difficult to assign specific ages or sexes to pathologies in such material, making it harder to assess the separate possible factors influencing individual cases. Complete skeletons can often give more detailed, nuanced assessments.

Animal Paleopathology, Fig. 2 Cattle metacarpal from Roman Canterbury (England) displaying degenerative changes to the distal epiphysis, with splayed distal condyles and peripheral exostoses. (Photo: author)

Animal Paleopathology, Fig. 3 Identifying horses used for transport: above – the position of the bit relative to the mandible in the horse's mouth; below – both reactive new bone deposition and bone destruction on left and right mandibular diastemata of a horse from Iron Age Danebury (England) interpreted as a bit-induced pathology. (Photo: author)

Cultural attitudes towards animals can also be revealed through the study of pathologies (MacKinnon 2010). Traumatic injuries, for example, can give insights into possible cases of accident, abuse, "occupational" injury, care, and treatment of "pets." Dogs, for example, may be susceptible to both abusive injury by humans and "occupational" injuries received during hunting or herding (Fig. 4). In such studies, recorded fracture prevalence rates will be an underestimate of the true prevalence, and it is also difficult to distinguish between accidental and deliberate injuries (which is most reliably assessed through cases where traumata distributions are studied in complete skeletons) (Groot 2008). Again, to interpret archaeological data, it would be useful to have modern control data for known populations, such as the prevalence of fracture rates in working populations of dogs (Thomas and Mainland 2005).

Environments and Living Conditions

Knowledge of past animal health and disease articulates with, and informs on, that of broader ecology and environment. This can encompass the broader regional environmental context of the animals (e.g., climate and ecology) and also "local" context (e.g., housing, penning, etc.). Diet, a key aspect of animal ecology, directly affects skeletal development.

In recent years, a considerable research focus has been directed at recording and interpreting finds of enamel hypoplasia – an interruption or disturbance in the formation of enamel (Fig. 5). This developmental defect is associated with physiological stress during the growth of the tooth crown. Research has shown that it can be due to a range of factors causing stress on the animal, especially developmental (e.g., weaning), nutritional (e.g., seasonal malnutrition), and disease (e.g., parasite load). In zooarchaeology, most work has been undertaken on the low-crowned

Animal Paleopathology, Fig. 4 Photograph (left) and X-ray (right) of a healed double fracture of a Roman right dog radius and ulna from Tiel-Passewaaij (the Netherlands). (Photo: courtesy of Dr. Maaike Groot)

Animal Paleopathology, Fig. 5 Linear and pitlike enamel hypoplasia on an Iron Age horse lower third molar (M_3) from Tsengel Khairkhan (Mongolian Altai). (Photo: author)

teeth of pigs; however recent work has begun to address the study of enamel hypoplasia on high-crowned species, such as caprines (sheep and goats) (Upex and Dobney 2012). The prevalence of enamel hypoplasia, for example, has been shown to vary according to climatic and ecological factors in a study comparing modern caprine teeth between a semiarid and a (moister) mesic environment in Kenya (Balasse et al. 2010).

Studies of enamel hypoplasia can also inform on animal husbandry. In the study of pig remains covering some two millennia at Neolithic Çayönü Tepesi, in south-east Turkey, Ervynck et al. (2002) identified a gradual increase in enamel hypoplasia through time, along with a trend towards younger animals at death and smaller body size. They interpreted this as a gradual increase in physiological stress in pig populations due to the domestication process and animal husbandry pressures.

Markers indicative of the animals' physical environment may be preserved on the bones. The condition known as "penning elbow" – consisting of new bone (osteophyte) deposition on the lateral side of sheep humero-radial joints – is so-called as it is often considered to be a result of trauma to the outside of the joint from husbandry practices such as penning or handling (Baker and Brothwell 1980: 127; Upex and Dobney 2012; 202–203). However, recent work on comparative modern sheep populations from North Ronaldsay (Scotland) indicates that the incidence of these lesions may not be related exclusively to husbandry practices but also to environment, joint morphology, and possibly age (Clark 2009). This study of sheep from two contrasting environments on the island indicated that the lesion may also be related to the environment and that repeated minor shocks, as might be expected from movements over rocky ground, may produce the lesion.

Animal Breeding and Husbandry

Animal management and husbandry techniques lie at the intersection of economic and cultural decisions, domestic animal physiology and behavior, and local (and wider) environmental contexts. Evidence for these practices, as discussed above, can leave various traces in animal skeletons linked to both individual lifetime events (e.g., weaning) and habitual lifestyle and behavior (e.g., grazing terrain). Other conditions may potentially contribute to understanding of the housing and feeding of animals, such as evidence for rickets or malnutrition (Baker and Brothwell 1980: 43–52). At the population level, selective breeding for certain desired traits can have detrimental effects by the unconscious concomitant selection of other detrimental congenital traits which can be identifiable in skeletal remains (Baker and Brothwell 1980: 40–42; Upex and Dobney 2012: 204–205).

Infectious Diseases and Disease Ecology

Changes in disease ecology and the incidence of infectious diseases affecting humans and animals will have been important consequences of changing human-animal relationships through time. A range of cultural, social, biological, and environmental variables will have impacted upon the epidemiology of infectious diseases in the past. Examples of the significant effects of the transmission of infectious organisms between contiguous animal and human communities are well known, as in the medieval plague epidemics in Europe caused by the bacterium *Yersinia pestis*.

Animals are, and have been, an important vector for the transmission of infectious diseases to humans, and the study of animal paleopathology can therefore inform our understanding of the disease ecology of past human communities. Domestication events can be seen as pivotal moments in these stories, for example, the number of shared diseases between humans and domestic animals increases in relation to the length of time since domestication (Horwitz and Smith 2000). The intensification of human-animal relationships through the domestication processes provided the routes for disease transmissions. The health implications of infectious diseases for past animals may also potentially provide valuable insights into past economies (e.g., losses associated with illness and death among domestic animal populations) and environments and living conditions (e.g., contact among and between various domestic and wild animal species).

Our ability to explore these relationships is limited by what is identifiable from the archaeological record. For example, a case of tuberculosis (caused by infection by one of the members of the mycobacterial tuberculosis complex) may cause bony changes to the skeleton of an animal, whereas one of anthrax (caused by the organism *Bacillus anthracis*) would not. Further, only a small proportion of animals infected by an infectious organism might show evidence of bony changes (when these do occur – as in the case of tuberculosis), suggesting that what is visible in the archaeological record underrepresents the true prevalence rate (Upex and Dobney 2012: 196). As mentioned above, the taphonomic histories of most animal bone assemblages mitigate against the identification of diseases (Bartosiewicz 2008). However, in some cases, we have complete, well-preserved animal skeletons with lesions preserved suggestive of infectious disease. Even then it is often the case that gross morphological analysis can often only indicate nonspecific infections, as identifying the causative agent based on structural changes within bone alone is problematic given the lack of specificity of these changes for the various pathogens (Bendrey et al. 2008). Beyond this it may only be with the application of DNA analyses that a specific agent may be positively identified (Spigelman et al. 2012), although epidemiological models can be used to generate hypotheses about factors promoting the potential circulation and maintenance of pathogens within past populations (Fournié et al. 2017).

Future Directions

Although still a relatively young discipline, animal paleopathology is capable of delivering valuable and unique insights into a range of past human-animal-environment interactions. Studies are most powerful and effective when linked into the broader archaeological context and integrated with other methods. The foundation for the future of animal paleopathology will be built on a few key practices: an emphasis on the description of lesions (not just diagnoses) in publications, in a quantifiable manner, and the routine calculation of prevalence rates. Ideally, recorded conditions should be analyzed within the background of the normal elements and in relation to the other recognized osteological anomalies in that species in the analyzed assemblage (Clark 2009).

It is the identification of variation in gross morphology of bones and teeth that is the core method in the study of animal paleopathology, but increasingly the application of multiple techniques to specimens will help to produce robust differential diagnoses including radiology, microscopy, histology, and genetic analyses. Microscopic study of bone microarchitecture can contribute important perspectives on the nature and timescale of pathological manifestations. Undoubtedly, recent and future advances in ancient DNA research will contribute significant results to the study of ancient diseases and their ecology, although there is continued debate over both methods and results (Spigelman et al. 2012). Further understanding of skeletal abnormalities must be based on the distribution and expression of such conditions in modern control populations (e.g., Bartosiewicz et al. 1997; Bendrey 2007), otherwise interpretations of lesions in the archaeological record risks being nothing more than speculation. The discipline must continue to test and refine methodologies and assess and compare the expression of abnormalities in different archaeological as well as modern populations.

Annapolis: Historical Archaeology

Jocelyn E. Knauf[1,2], Amanda Tang[1], Kathryn H. Deeley[3] and Mark P. Leone[1]
[1]Department of Anthropology, University of Maryland, College Park, MD, USA
[2]National Museum of American History, Smithsonian, Washington, DC, USA
[3]School of Liberal Arts, Georgia Gwinnett College, Lawrenceville, GA, USA

Brief Definition of the Topic

Annapolis, first settled in 1649, is located on the Chesapeake Bay and is the current capital of the state of Maryland. Initially centered on the Chesapeake tobacco economy, Annapolis is known today for its maritime and heritage tourism industries. The city served as the short-lived capital of the United States from 1783 to 1784 and has been the home of the US Naval Academy since 1845. Annapolis has become a tourist destination due to its seventeenth-century town plan and surviving impressive eighteenth-century and vernacular nineteenth-century buildings. A formal archaeological program, Archaeology in Annapolis, began in 1981 through collaboration between the University of Maryland, College Park, Historic Annapolis Foundation, and City of Annapolis. Since that time, Archaeology in Annapolis has excavated sites ranging from elite colonial houses and gardens to early twentieth-century houses of middle- and working-class people from different racial backgrounds. Through archaeological interpretation, the history of enslaved and free African-American life became a more publicly understood part of the city's official histories.

Archaeology in Annapolis seeks to understand the city as a whole, interpreting its history and class structure. Early work focused on the ability of archaeology to understand the development of the culture of capitalism. This work is exemplified by Mark Leone's study of the William Paca Garden, Leone and Paul Shackel's examination of individuation and standardization of material culture, and Barbara Little's study of the Jonas and Anne Catherine Green Print Shop. As the early goals were to democratize archaeology and challenge a world created by capitalism, through the work of Parker Potter, Archaeology in Annapolis also became an experiment in public archaeology. Using open excavations, museum exhibits, newspapers, local television, and community education, the project sought to integrate critical theory with the aim of politicizing and making change in the present.

During the early 1990s, the project began to excavate the homes of the city's free African-American community and those of middle- and working-class residents of European descent. Guided by community-based anthropology, much research was carried out in consultation with minority communities. Working especially with politically or socially disfranchised groups, the hope was to present alternatives to official historical narratives. This work is exemplified by Paul Mullins' and Mark Warner's studies of the 1847 Maynard-Burgess house, the home of a free, middle-class African-American family, where they examined the effects of racist experiences, labor structure, and class through material consumption. In a comparative study, Kathryn Deeley continued exploring these intersections at the James Holliday house, examining the connections between table settings, women's occupations, and class within the African-American community in Annapolis. Jocelyn Knauf wrote about the ways that normative ideas about domestic etiquettes and management, public health behaviors, and appropriate use of urban space were negotiated by residents of a diverse area of the city. Hannah Jopling describes how African American families tenaciously struggled to gain their equal rights at the same time they enriched their own community in 20th century Jim Crow Annapolis.

Also illuminating a history of Annapolis made for class purposes, Parker Potter Jr. and Christopher Matthews have shown how the city's current look is tied to the nineteenth and twentieth centuries through the making of and use of landscapes and the reconstruction of them. They offered a critique of the uses of archaeology and historic preservation. These landscapes extend to include the infrastructure of the city's utilities. Matthew

Palus's dissertation articulates how infrastructure changes in the early twentieth century reflected racial and class inequalities throughout the city. His dissertation is a particularly full exemplification of these aims of the members of Archaeology in Annapolis.

Overall, archaeology has sought to understand how material culture is tied to power relations, the creation of class, and identity construction within the context of a single city. This has included the study of the transition to a capitalist economy, the techniques of racism, and examination of the city's historic preservation industry.

Anozie, Fred

Emuobosa Akpo Orijemie
Department of Archaeology and Anthropology, University of Ibadan, Ibadan, Nigeria

Basic Biographical Information

Information on Prof. Fred A. Anozie is extremely scarce. Prof. Anozie, as he was popularly called, was an astute Nigerian archaeologist whose name rang (still rings) bells within the archaeology space in and outside Nigeria. There is, as yet, virtually no information about his early years. But it is known that as early as 1977, Anozie had published a preliminary report of excavations in Aguleri, a village in Southeastern Nigeria (Nzewunwa 1983).

Between 1978 and the 1980s, Prof. Anozie conducted extension research in Igboland and quickly became recognized as a notable archaeology scholar in Nigeria and West Africa. Most of his research sites were based in eastern Nigeria with some of the most popular being the Ezi-Ukwu rockshelter near Afikpo, the iron-smelting sites of Umundu and Lejja, and Ugwuele in Uturu Okigwe local government area in Imo State, Nigeria (Nzewunwa 1983).

Major Accomplishments

Like Dr. N. Nzewunwa, the fact that he worked with Prof E.J. Alagoa for many years and coauthored the book: *The early history of the Niger delta* is a testimony of his competence in

the field. In addition, he and Prof. Chikwendu V.E. took over the mantle of leadership for the direction of archaeological research in Eastern Nigeria with the exit of Prof. D.D. Hartle who worked extensively in Igboland in the mid-twentieth century.

He was a prominent member of the Archaeological Association of Nigeria (AAN) until his unfortunate death in 2006.

Anquandah, James

Benjamin Kofi Nutor
Department of Anthropology, University of Texas at Austin, Austin, TX, USA

Basic Biographical Information

Professor James Kwesi Anquandah (Fig. 1) was one of the earliest and longest serving Ghanaian archaeologists. He was born on April 10, 1938 and obtained his Cambridge School Certificate from the Achimota School in Accra, Ghana, in 1957 and Cambridge Higher School Certificate in 1959. Prior to obtaining his diploma certificate in Archaeology from the University of Ghana, Legon, in 1965, professor Anquandah had studied for his Bachelor of Arts (B.A.) degree in history at the same university from 1960 to 1963. In 1967, he received his Master of Letters (M.Litt.) from the University of Oxford, UK, and worked as a research assistant at the Pitt-Rivers Museum, University of Oxford, between 1966 and 1967.

Anquandah, James, Fig. 1 James Anquandah

Before joining the academia, Professor Anquandah worked at the state-owned Ghana Broadcasting Service (GBC) as Programmes Officer (1959–1960) and later as Senior Producer (1972–1973) of content pertaining to the history, culture, and heritage of Ghana. He began his career at the University of Ghana as a research fellow in African Studies and Archaeology (1973–1975) and then as lecturer at the Department of Archaeology (1975–1978) and rose through the ranks. He was promoted to senior lecturer (1978), associate professor (1988), and professor in 1994. Professor Anquandah had a wide array of experience in teaching and researching African Archaeology and has about 50 publications. His areas of specialization include Archaeology of Ghana/West Africa, Archaeology of the Nile Valley, Historical Archaeology, Art History of Ghana, and Palaeo-Historical Demography.

At the University of Ghana, Professor Anquandah held several positions, including Head of Department of Archaeology (1976–1977; 1981–1993) and Dean, Faculty of

Social Studies (1991–1997). He also acted briefly as pro-vice chancellor of the University from January 1996 to February 1996. He served on various boards and committees of the university including Academic Board, Faculty Board, and Executive Committee. He was the curator of the Archaeology Museum, University of Ghana, Legon, from 1974 to 1998 and served as member of Ghana Museums and Monuments Board (GMMB) from 1995 to 1999 and 2010 to 2012.

He was a visiting professor at the University of Pisa, Italy in 2002 and visiting professor at the New York University (Ghana Campus) in Art History (2008–2017) and served as external examiner doctoral theses from the College of Art, Kwame Nkrumah University of Science and Technology, Kumasi-Ghana, from 2006 to 2017. After serving 10 years (1998–2008) post-retirement contract at the Department of Archaeology and Heritage Studies, University of Ghana, James Anquandah continued to teach on part time until he passed away in September 2017.

Major Accomplishments

Professor Anquandah was instrumental in the training of most of the current generation of Ghanaian archaeologists at the University of Ghana and elsewhere. He played a vital role in the survival of the Department of Archaeology by resisting attempts by university authorities to scrap the department in the 1990s following some restructuring exercises embarked on by the University. His contribution to the now vibrant Department of Archaeology and Heritage Studies, University of Ghana (the only such department in Ghana and one of the earliest established in Sub-Saharan Africa), cannot be overemphasized.

As one of the earliest Ghanaian archaeologists, Professor Anquandah became the first Head of Department of Archaeology at the University of Ghana, after apprenticing under, and later working with, expatriates such as Peter Shinnie, Oliver Davies, and Merrick Posnansky. His commitment to research and publication aimed at deepening knowledge about the prehistory, historical archaeology, and arts history of Ghana remains one of his greatest achievements. His pioneering works as an indigenous archaeologist (Anquandah 1981, 1987, 1998, 1999, 2003, 2012, 2013, 2014) are good insider's contribution to Ghanaian Archaeology and African Archaeology at large. He won the Ghana Book Development Council award in 1983 for the publication of his book (Anquandah 1982) titled *Rediscovering Ghana's Past*. In 1987, he successfully mounted an exhibition on Ghana's Arts at Porte de Versailles in Paris.

Between 1994 and 2001, Professor Anquandah served as the coordinator of the management committee of the Ministry of Education Secretariat Universities of Ghana Research Fund. As the Chairman of the Scientific Committee, National Commission on Culture (2004–2008), he among other things ensured the creation and maintenance of a vibrant website for the commission which serves as a good reference point for the understanding of certain aspects of Ghana's culture and cultural institutions.

He worked tirelessly as chairman of the research unit of Ghana's National Slave Route Project at the Ministry of Tourism from 1999 to 2017. The unit's efforts culminated in the publication of one of the most comprehensive books (Anquandah 2007) on the trans-Atlantic slave trade in Ghana.

Antarctica: Historical Archaeology

Michael Pearson[1] and Maria Ximena Senatore[2,3]
[1]Heritage Management Consultants, Canberra, ACT, Australia
[2]IMHICIHU-CONICET, Instituto Multidisciplinario de Historia y Ciencias Humanas, Universidad de Buenos Aires & Universidad Nacional de la Patagonia Austral, Buenos Aires, Argentina
[3]CONICET- INAPL and Universidad Nacional de la Patagonia Austral, Buenos Aires, Argentina

Introduction

Historical archaeology in Antarctica has been largely driven by the needs of heritage resource management. Polar heritage sites can be defined by, or have their significance enhanced by, archaeological remains, and the archaeological study of aboveground evidence and buried deposits has long been used in researching and conserving such sites in Antarctica.

In Antarctica, archaeological sites are rare commodities. Human presence on the continent and its surrounding islands has been relatively recent, brief, infrequent, and widely scattered. The range of human activities – exploration, sealing, whaling, and scientific research – has been very limited, and sites often relate to a single use at a single point in time. These sites have immense archaeological potential and, at the same time, are unique elements of the world's cultural heritage. They are also very expensive to study, given their isolated location and difficult access, severe climatic conditions, and the difficulties in excavating frozen deposits. These considerations dictate that the benefits of archaeological programs in Antarctica have to be clearly demonstrated in order to gain support, and to date, most funding has been associated with broader heritage conservation or environmental remediation efforts.

Professional historical archaeology has been practiced in Antarctica and the sub-Antarctic islands since the late 1970s. Archaeologists from Argentina, Australia, Brazil, Chile, France, New Zealand, South Africa, the United Kingdom, and the United States of America have participated in archaeological programs of survey, recording, or excavation. The objective of this work in the past has primarily been the identification and conservation of historic sites and in particular historic buildings, but in recent decades, substantial work has been done on sealing-era sites in the South Shetland Islands, with more academic research-driven objectives (for a short history of archaeology in Antarctica, see Pearson 2011a).

Definition

"Antarctica" is defined as being the area south of 60° south latitude (the area encompassed by the Antarctic Treaty), and for the purposes of archaeological research, the isolated peri- and sub-Antarctic islands of the Southern Ocean are included. All archaeology on the Antarctica continent and immediate peri-Antarctic islands is historical archaeology, as there is no evidence of any prehistoric contact with the continent. There is, however, recent evidence of prehistoric Polynesian visitation or settlement on the sub-Antarctic Auckland Island, south of New Zealand, and Campbell Island in the same region remains to be investigated (Dingwall et al. 2009).

Key Issues/Current Debates/Future Directions/Examples

The vast bulk of the archaeological work in Antarctica has been undertaken in relation to the removal of ice from inside and around historic huts and the excavation, often through ice, of accumulated material inside huts and of stores boxes and caches outside huts. Despite being targeted at practical conservation works, this research has produced an accumulated record of the activities and material culture of, particularly, Heroic Era exploration parties (1897–1922).

In the case of sealing and whaling sites on the sub-Antarctic islands and the peri-Antarctic South Shetland Islands, the focus has been on establishing the presence and form of shelters and work areas, again largely related to the long-term conservation of this heritage resource, but also providing information about sealer's and whaler's domestic subsistence and work activities not available in the usually scant documentary sources (Figs. 1 and 2). The work of Senatore and Zarankin in the South Shetland Islands has moved archaeology into more theory-driven research questions (e.g., Senatore and Zarankin 1999; Zarankin and Senatore 2005, 2007; Zarankin et al. 2007).

The range of conservation-related archaeological work has included:

The retrieval of artifacts related to known historical parties

The direct understanding of the construction of buildings and sites, their historical sequencing, and use

The understanding of sites in the context of other, like, sites

Ascertaining the survival and research value of artifacts in the light of Antarctic risks such as "wallowing" by elephant seals (e.g., Townrow

Antarctica: Historical Archaeology, Fig. 1 Map of South Shetland Islands showing the location of archaeological sites of sealers and whalers occupation in the nineteenth century

Antarctica: Historical Archaeology, Fig. 2 Sealer/whaler archaeological site in Livingston Island, South Shetland

1989) and erosion caused by penguin rookeries and extreme weather events (Pearson et al. 2008.

For nonstructural sites, such as sealing sites, better understanding of their characteristics so other sites can be identified (e.g., determining if artifact types differ from inside and outside now-collapsed shelters, so former shelter locations can be identified from artifact scatter patterns)

Isolating the factors influencing the deterioration of archaeological sites over time

Work asking broader research questions has included:

Determining if the archaeological remains provide substantive evidence of heritage significance not available from other sources (such as the lifestyle and experiences of nineteenth-century sealers, e.g., Lazer and McGowan 1990: 15)

Determining the ethnic origin of sealers (e.g., McGowan 2000: 69)

Using evidence to see if sites found in different locations originated from the same sealers (e.g., Hughes and Lazer 2000: 73)

The relationship of sealing to global industrial developments and economic networks (Senatore and Zarankin 1999; Zarankin and Senatore 2005, 2007)

In the Antarctic regions, the documentary evidence of human activities is sometimes far less helpful in understanding the past than it can be in more temperate climates. The Heroic Era exploration sites are usually well supported by journals, diaries, inventories of gear, and even photographs. There are, however, few surviving sealing logs and journals, and there are few detailed inventories of sealer's gear and stores, nor are there many instances where a specific site can be related to a specific historically documented party. The life experience of individual sealers is little recorded. The interpretation of the aboveground sites and excavated finds and data can provide "physical history" to augment a scant documentary history of this important period of human interaction with the continent, quite apart from archaeology's potential to address broader research questions.

Archaeological excavation destroys, at least in part, the sites it studies, and human occupation sites in Antarctica are rare. They are of high research value and of high heritage value, are vulnerable to human (including archaeological) and natural disturbance, and are very difficult and expensive to study. It is therefore imperative that archaeologists understand the multiple values of the sites they wish to study and formulate research strategies that maximize the benefits of their work in the unusual Antarctic context.

Anthracology: Charcoal Analysis

Rita Scheel-Ybert
Programa de Pós-Graduação em Arqueologia, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brazil

Introduction

Anthracology is a transdisciplinary field of knowledge that applies to the study of ancient or extant charcoal macroremains. This discipline was developed in close association with Archaeology, but contributes to different fields such as Palaeoecology, Palaeobotany, Botany, Forestry, and Geology.

In Quaternary and pre-Quaternary sedimentary deposits, charcoal allows reconstruction of the palaeovegetation and palaeoclimate.

In archaeological sites, it provides palaeoecological data while also testifying the usages that past populations made of woody plants. This discipline sheds light on several issues of

importance to Archaeology, such as the past landscape, dwelling space, site catchment area, fuel economy, use of wood in domestic and ritual contexts, among others. By these means, it allows a better understanding of ancient ways of life.

Extant charcoal is studied in a taxonomic approach (charcoal anatomy), or in association with foresters as a means of reducing illegal wood extraction from native biomes.

This young field of study has ongoing theoretical and methodological developments in all of its lines of research. It is particularly dynamic in its archaeological strand.

Definition

Anthracology is the analysis and identification of charcoal based on wood anatomy.

This term is employed both in a broader sense (all branches of the discipline) and to denote studies in archaeological context in general. Some authors, however, will refer to the latter as "Archaeoanthracology."

Other branches of this discipline are specifically designated as:

- "Pedoanthracology" or "Geoanthracology," denoting the analysis and identification of charcoal of sedimentary origin (soils, palaeosoils, sedimentary deposits)
- "Pre-Quaternary Anthracology," reserved for studies of pre-Quaternary charcoal remains
- "Dendroanthracology," indicating the application of dendrological techniques to charred fragments, especially wood diameter estimates

Although some English speakers favor the term "Charcoal analysis" to encompass all of these approaches, "Anthracology" is more precise and already widespread in the international literature (e.g., Scheel-Ybert 2000; Théry-Parisot et al. 2010; Damblon 2013; Dotte-Sarout et al. 2015). We should therefore distinguish "Anthracology," the analysis of macrocharcoal based on wood anatomy, from "Charcoal analysis," which is largely employed to designate the analysis of microcharcoal in sedimentary context. While the first aims for archaeobotanical and palaeoecological studies through taxonomic identification, the second aims for the identification of past fire events or periods of fire activity through quantification of microremains.

Historical Background

The identification of plant species from the analysis of charred remains is quite ancient. The first known studies dealt with archaeological charcoals and date from the second half of the nineteenth century, in Europe (e.g., Heer 1866). The twentieth century witnessed a growing interest of archaeologists, especially from the Mediterranean basin, for charcoal identification and the ensuing possibility of landscape reconstructions. But the first study presenting explicitly paleoecological interpretations based on archaeological charcoal was carried out in Britain (Salisbury and Jane 1940). It was harshly criticized on the grounds that cultural factors (species selection) and differential preservation preclude adequate representation of the natural vegetation in archaeological context.

It was only from the 1960s that a stronger interest of botanists and wood anatomists in archaeological charcoal and their palaeoecological interpretation, particularly in France, laid the foundations for an important advance of the discipline. In this context, Couvert (1968) was the first to recognize that anthracological analysis offered palaeoecological data which would be even more accurate than those obtained from pollen analysis (actually, these disciplines are complementary. Palynology offers information on different plant seres – trees, herbs, epyphites etc. – in a regional scale, while anthracology provides data on woody plants only, but at a local level. Confrontation with phytosociological data is more straightforward for the latter. Taxonomic determination, often at the species or genus level in charcoal, is also generally more accurate than in palynological studies).

In these early studies, sampling was essentially restricted to hearths charcoal. The methods of analysis (wax, resins, or paraffin embedment,

microtome cutting, thin sections mounting) were extremely time-consuming, and often produced poor and few sections. Consequently, very few charcoal pieces were analyzed and the results rarely allowed more than small floristic lists.

The multiplication of analyzes and the emergence of Anthracology as a proper discipline was made possible through the establishment of an original methodology: manually fracturing charcoal fragments to expose fresh anatomical sections, followed by observation under incident light using reflected light microscopes. This method allowed the identification of a large number of specimens in a much shorter time (e.g., Western 1971; Vernet 1977) and led to the possibility of quantitative studies and to the adoption of meaningful palaeoecological perspectives.

The French Jean-Louis Vernet was responsible for a significant improvement in the development of Anthracology. In a major research center founded at the University of Montpellier, he encouraged the first systematic studies of archaeological charcoal and contributed to establishing the theoretical and methodological bases of the discipline. Under his influence, significant research was carried out in the Mediterranean, particularly in France and the Iberian Peninsula, and anthracological research advanced to several countries in Europe and later to other continents.

From the 1980s, the discipline was marked by an increasing concern about the recognition of the palaeoecological significance of archaeological charcoals, the establishment of appropriate sampling strategies and analytical methods, and the need for statistically reliable analysis and for experimentations aiming to understand carbonization and postdepositional processes. Based on these studies, many anthracological analyses proved the validity of palaeoecological reconstructions based on archaeological charcoals, despite the cultural factors and differential preservation issues that might influence the samples.

At the same time, another line of research (Pedoanthracology) was also developed in France, under the guidance of Michel Thinon, from University of Marseille. Later, charcoal analysis in Quaternary and pre-Quaternary sediments spread throughout Europe and North America, aiming essentially at the reconstruction of palaeoenvironmental and palaeoclimatic changes.

From the 1990s, concurrently in France and Germany, a branch of anthracological research was directed towards the estimation of wood diameters. Dendroanthracology, based on the premise that the election of wood diameters is probably as relevant as that of wood species, provides interpretations concerning the availability and choice of wood in different contexts, as well as on vegetation structure (e.g., Marguerie and Hunot 2007; Ludemann 2010).

Currently, a great number of publications in many parts of the world attest of the vigor and advancement of the discipline in its different approaches. Important compilations of works developed by anthracologists over the years have been published in the actes of five of already six international conferences (Vernet 1992; Thiébault 2002; Fiorentino and Magri 2008; Badal et al. 2012; Damblon et al. 2013). More extensive references and more detailed accounts on the history of Anthracology may be found elsewhere (e.g., Asouti 2006; Théry-Parisot et al. 2010; Dotte-Sarout et al. 2015; Scheel-Ybert and Gonçalves 2017).

Key Issues/Current Debates

Anthracology is a young discipline and as such its theoretical and methodological bases are still under construction. Some key issues under debate in the present and past few years, particularly those related to studies in archaeological context, are discussed below.

Significance of Charcoal Deposits in Archaeological Sites

Anthracological interpretations are based on two kinds of charcoal deposits, which must be distinguished during the archaeological excavations and carefully collected.

Concentrated charcoals are related to specific activities (domestic or specialized hearths, kilns, charred artifacts, etc.). Features containing concentrated charcoal normally have had a brief

utilization in time or bear the remains of only the last charring event. Thus, they imply in a short-term deposition – and therefore a sample that is not representative of the plant environment as a whole (Chabal 1997). Analysis of such deposits usually reveals species-poor assemblages and provides only palaeoethnobotanical information. They may allow identification of firewood acquisition practices (distinction of intentional wood selection from random wood gathering), but only through the analysis of a large number of features.

Dispersed charcoals derive from the scattering of charcoal pieces originated from the many different burning activities performed in a site or from the periodical cleaning of fireplaces – thus representing a long-term deposition (Chabal 1997). These are the remnants of numerous wood gathering events over time, probably with multiple objectives. These samples usually contain species-rich assemblages and as such provide good representations of the plant environment.

Palaeoecological Reliability of Archaeological Charcoal

Palaeoethnobotanical reliability of archaeological charcoal is never questioned. However, a common criticism anthracologists still meet is that archaeological samples could not possibly provide palaeoecological reconstructions due to cultural wood selection and to postdepositional differential preservation.

The reliability of these studies, however, has already been amply demonstrated. Diligent methodological and statistical studies largely fostered by the French Lucie Chabal were essential in establishing the validity of this approach (e.g., Chabal 1997; Théry-Parisot et al. 2010).

The first main argument to be advanced was the low species selectivity of domestic firewood gathering (Vernet 1977; Shackleton and Prins 1992; Chabal 1997). Indeed, many authors agree that domestic firewood, most usually, is randomly gathered around the settlement. The corollary is that all the species present in the surrounding vegetation would be collected as fuelwood in (approximatively) direct proportion to their abundance in the environment. Since the site occupation length is directly correlated to firewood gathering and to the surface of the site catchment area, long-term deposition of domestic charcoal is a good proxy to the surrounding vegetation.

More recently, cultural aspects related to fire function also came to be considered. Fire, in traditional societies, had several different functions (such as heating, cooking, lighting, drying, smoking, transforming raw materials, keeping animals away, taking part in ceremonies or ritual practices). For each one of these functions, different woods might be chosen. Théry-Parisot et al. (2010) argue that the notion of "good fuel" is closely related to the usage intended for each particular fire, i.e., if the goal is to get flames, embers, smoke, heat, etc. Since the essences have different properties, one good fuel would not exist, but different fuels were needed for different purposes. In addition, one must consider that wood properties can change according to the essence, but also according to log diameter and wood state (dried, fresh, rotten, etc.). The corollary is that there is a wide range of wood choices (or non-choices) that might be associated to each fire function in a human settlement. Once again, on the condition of analyzing the remains of an occupation that has lasted for a sufficiently long time, it is likely that all the species in the different vegetation types around the settlement will have, sooner or later, a chance to be collected, charred, and therefore preserved as charcoal.

The arguments presented above are not mutually exclusive. Hence, one can conceive that people in the past gathered and concentrated wood samples in the archaeological site, on the same measure that the wind concentrates pollen grains in lakes sediments. In both cases, under-representation or over-representation of some taxa is expected. Still, the most frequent species in the environment tend to be better represented in the sediments than rarer ones.

Notice that different vegetation communities may be recognized in an anthracological assemblage, as the plants associated with each vegetation type can be identified by ecological criteria. Similarly, ecological criteria may help identifying over-representation of taxa due to positive selection. Conversely, under-representation due to negative selection (avoidance of firewood because of

undesirable fuel properties or cultural taboo) may be much harder to recognize.

Currently, most authors agree that reliable palaeoecological information should be based on the analysis of "synthetic" deposits, which combine remains of the different vegetation types existing around the settlement during the occupation (Théry-Parisot et al. 2010). Those are the dispersed charcoals, but also specific concentrated charcoal features. The latter include hearths or kilns associated with long-term activities, that is to say, that have been repeatedly supplied with wood fuel. These deposits may be identified by archaeological criteria and by their high species diversity. However, in most circumstances, analysis of the dispersed charcoal might be necessary to validate the interpretations proposed.

Charcoal kilns, although representing short-term activities, are also high diversity synthetic deposits. They are related to the cutting of entire forest parcels (cf. Ludemann 2010) and may therefore be interpreted in an ecological approach.

Palaeoecological reliability of archaeological charcoal analyses is supported by arguments largely demonstrated both in temperate (Vernet 1977; Chabal 1997) and in tropical sites (Scheel-Ybert 2000): (1) the high taxonomic richness/diversity of samples, (2) the strong correlation between different analysis, i.e., the similarity of anthracological results in contemporary neighboring sites and between different layers/samples of the same site, (3) the strong correlation between different proxies (e.g., charcoal, pollen grains, phytoliths), (4) the strong correlation of anthracological spectra with extant vegetation types.

Taphonomy/Postdepositional Issues

In a strict sense, "taphonomy" refers to the study of the processes by which biological remains become fossilized – in the present case, the processes through which charcoal of human or natural origin become incorporated to the sediments after the extinction of fire. Anthracologists dealing with archaeological charcoal, however, have proposed a broader definition of this term, in order to take into account the many human activities and natural processes affecting this ecofact, from wood gathering to the charcoal analysis (Théry-Parisot et al. 2010).

In this sense, "taphonomy" comprises a series of processes influencing the reconstruction of the original vegetation from the analyzed charcoal assemblage: (1) cultural practices (firewood gathering, fuel management, wood selection, taboos, fire functions, fireplaces management), (2) combustion (carbonization, mass loss, anatomical changes, differential fragmentation, charcoal preservation), (3) depositional and post-depositional processes (anthropogenic factors, sedimentation, bioturbation), and (4) archaeological/anthracological procedures (excavation, sampling, identification, quantification methods).

The first three levels of processes lie beyond any concrete action of the anthracologist, but can be better understood through experimental tools, and ethnographical and theoretical models (Dotte-Sarout et al. 2015). The fourth level can be controlled by an effective sampling methodology, rigorous laboratory practices, and adequate statistical treatment.

Nevertheless, despite all the processes affecting charcoal from firewood collection to its analysis (human transport, physical transformations of carbonized wood, postdepositional processes, fragmentation, etc.), many results show that anthracology allows reliable reconstructions of local woody vegetation.

Sampling Procedures

Two sets of practices must be considered for anthracological sampling: field sampling and laboratory analysis.

In the field, the archaeologist/anthracologist must consider the different existing charcoal deposits. Concentrated charcoals in archaeological features are much more conspicuous during the excavation and have historically been preferentially collected. But the choice, by the excavator, of the larger, more concentrated or more easily recognizable charcoal in the field, is a bias that would unavoidably lead to interpretation errors. Hence, systematic sampling of the dispersed charcoal from archaeological sediments is paramount. Although they frequently go unnoticed by the untrained eye, dispersed

charcoals are the basis of palaeoecological reconstruction and stand as a control for palaeoethnobotanical interpretations.

Anthracological field sampling must be planned in order to guarantee the reliability of palaeoecological and palaeoethnobotanical interpretations and the reproducibility of the results. The site surface should be extensively sampled. Under the best of circumstances, sediment samples from one-fourth to the entirety of each square meter, in each decapage, are collected (Chabal 1997) (Fig. 1). But the sampling estrategy may vary depending on the possibilities of the field and the layers' richness in charcoal. For instance, one might collect a bucket of sediment in alternating quadricules in each decapage or archaeological layer, if that guarantees a sufficient number of charcoal fragments for analysis, or else collect all the excavation sediments, exhaustively, when preservation is low or when the area of intervention is small.

When large surface excavations are not possible, sampling in trenches or profiles might allow acquiring important data, provided that the sediments are collected in natural/cultural levels.

Features containing concentrated charcoal (e.g., hearths and associated deposits, charred objects) should always be carefully collected, whenever possible with exhaustive sampling of the sediment.

In all circumstances, hand-picking must be avoided. Charcoal should be separated from the sediments by controlled sieving with mesh sizes down to 2 mm (4 mm being recommended by most authors). Flotation is by far the preferably recovering method, since it implies in greater efficiency, lesser effort, and is less aggressive for the material.

In the laboratory, subsampling will generally take place. Most authors agree that reliable interpretations must be based on samples of at least 200–400 fragments per archaeological layer or feature.

Some authors still argue that taphonomic bias in archaeological charcoal is too important to allow for quantitative analysis. They recommend that only qualitative analysis methods, such as ubiquity, should be employed.

Most anthracologists, however, agree that quantitative analyses are well founded. Yet a disagreement still subsists whether the mass or the number of charcoal fragments best represents the original proportion of the used firewood. But demonstrations and statistical analyses indicate that the relative proportions of taxa are much the same in weighing or counting of charcoal pieces (e.g., Chabal 1997). Counting remains, to these days, the most widespread method, for it is methodologically easier and more reproducible.

Once again, it is essential that all charcoal fragments from the sieve or flotation are collected and that fragments of all size classes are analyzed. The choice, by the analyst, of the larger or better conserved charcoal pieces would again introduce biases and interpretation errors, for it underestimates the sample diversity. Indeed, the outcome of fragmentation patterns statistically demonstrated is that larger fragment classes contain only the most frequent species, whereas most species, and all rare species, will be represented only in the smallest fragments (Chabal 1997).

Of course, "larger" and "smaller" are relative concepts and depend on the sample and the preservation conditions of each site. Gymnosperms of only 0.5 mm in side can be identified, but in general, the smaller the fragment, the harder the determination. Identification is usually possible down to 2-mm pieces, but the ideal minimum size of charcoal fragments to be determined is 4 mm. Smaller fragments usually lack a sufficiently large array of diagnostic features, resulting in difficult and time-consuming identifications, usually restricted to higher taxonomic levels.

Charcoal Identification/Carbonization and Structural Changes in Wood

Charcoal identification is based on the wood anatomy. Species-level identifications are quite common in temperate regions and low-diversity environments. In the tropics and areas of high biodiversity, genus-level identifications are expectable. In certain cases (for both contexts), determined by wood anatomy, only higher identification levels are possible.

The analysis of charcoal pieces is presently made under reflected light optical microscopes

Anthracology: Charcoal Analysis, Fig. 1 Schematic representation of the several steps of anthracological sampling (Adapted from Chabal et al. 2004). A. Concentrated charcoal shall be exhaustively sampled, independently of dispersed charcoal; B. Dispersed charcoal shall be systematically sampled, for instance, collecting all the sediments in a quarter of square meter at each decapage; C. The separation of charcoal from the sediments may be done by dry sieving, tank-sieving, or flotation, with meshes of 2–4 mm; wet sieving is to be avoided to prevent damage to charcoal pieces; D. Tank-sieving and flotation samples shall be allowed to dry naturally (no artificial heat source used), in order to preserve the anatomical integrity of charcoal; E. Charcoal samples may be stored in well-referenced plastic bags or hard containers; F. Concentrated and dispersed charcoal shall be analyzed separately; subsamples of 200–400 charcoal pieces of each feature or archaeological layer must comprise charcoals of all size classes

with brightfield and darkfield. Charcoal pieces are manually split according to the three wood structural sections: transverse, longitudinal tangential, and longitudinal radial (Fig. 2). Taxonomic determination of charcoal is done by comparing the anatomical structure with that of extant known wood species – consulting both descriptions and/or photographs from the literature or online databases, and samples from comparative collections.

Anthracology: Charcoal Analysis, Fig. 2 Charcoal anatomy of some tropical species; SEM images from the three wood structural sections (transverse, longitudinal tangential, longitudinal radial). A. *Aspidosperma olivaceum* (Apocynaceae). B. *Eremanthus goyazensis* (Asteraceae). C. *Bowdichia virgilioides* (Fabaceae Faboideae)

Charcoal anatomical characterization follows the standards of the International Association of Wood Anatomists, with very few discrepancies (Scheel-Ybert and Gonçalves 2017). This is possible because charcoal carries nearly all diagnostic wood characters.

However, charring/carbonization causes substantial mass loss and anisotropic shrinkage to wood – and many researchers expect that these changes induce significant structural changes in charcoal.

Thus, several studies have tried to assess these structural changes, through the analysis of charcoal obtained at different temperatures (e.g., Prior and Gasson 1993). All of them point in the same direction and demonstrate that (1) carbonization only causes minor quantitative changes in the original wood structure, and (2) the cellular organization is perfectly maintained on charcoal. These minor structural changes do not affect species identification, for their scale is similar to that which occurs between individuals of the same species for reasons intrinsic to the individual (e.g., trunk/branch thickness) or ecological factors (e.g., specimens collected at different plant formations, at the edge of a forest fragment or favored by higher water availability, etc.).

Dendroanthracology/Dendroanthracometry

Dendroanthracology consists essentially at estimating the minimum diameter of the charred wood. It aims at addressing issues such as wood gathering practices, wood choices, vegetation management, and evolution of forest structure under anthropogenic or climatic driving.

Different models were developed with this intent, mainly in France and Germany. There are qualitative (Marguerie and Hunot 2007) and quantitative models, the later using diameter stencils (Ludemann 2010) or image-analysis calculations (Dufraisse 2006). All are based on cross-section wood anatomy features: the curvature of annual growth rings and divergence of rays.

In the present, there is a large investment in the development of more precise protocols, in the establishment of models aiming at restituting the "real" diameter of the wood used and in the validation of coherent theoretical/methodological frameworks to these studies.

International Perspectives

Anthracological studies were initially developed in Europe and other temperate/Mediterranean regions. In consequence, most theoretical and methodological precepts were related to species-poor environments (e.g., Vernet 1977; Chabal 1997; Théry-Parisot et al. 2010).

The development of tropical anthracology began in the 1990s and was accompanied by diligent efforts to establish appropriate theoretical background and methodological protocols to species-rich biomes. The pioneer research, developed mostly in Brazil and later in the Australia/Pacific region, is marked by a strict concern with samples validity, statistical reliability, and the association of both palaeoecological and cultural interpretations (e.g., Scheel-Ybert 2000; Dotte-Sarout et al. 2015).

Contrary to the historical false antagonism that there seems to have existed between European "anthracology" (particularly focused in palaeoenvironmental reconstructions) and North-American "charcoal analysis" (of a more palaeoethnobotanical aim), tropical anthracology studies have been demonstrating that these two interpretative lines can be based on the same material. The human transport of wood from natural vegetation to the dwelling working, or ceremonial areas does not invalidate reconstructions of the past vegetation based on analysis of archaeological charcoal, for it can be assumed that past populations "sampled" the vegetation surrounding the site, leaving a record of the existing species as charcoal preserved in archaeological sediments. Likewise, the use of anthracology to reconstruct past environments should not overshadow the cultural information contained in the same sample.

While most of the theoretical/methodological principles developed for temperate and arid environments were proven to be valid in tropical biomes, a major distinction stands: Biodiversity.

In nontropical regions, of lower plant diversity – especially in Europe – wood anatomy is better known. Comprehensive wood anatomy references render the identification process much easier, and species-level determinations are frequent. In the tropics, determination accuracy is significantly lower. The two reasons for that are the high biodiversity (as the wood anatomy of several plants are similar to each other), and

the fact that the anatomy of tropical timbers is as yet poorly known, especially regarding non-commercial species. In consequence, species identification is harder and taxonomic precision is lower (frequently at genus level).

The precision of determination possible in regions of lower floristic diversity will probably never be achieved in the tropics. However, a decrease in uncertainty can be obtained by systematically taking into account a large number of anatomical features in each sample. This imposes a minimum size for the fragments studied (usually 4 mm), as well as the use of good comparative collections and databases as complete as possible.

Nevertheless, the results already obtained show that anthracological studies are perfectly applicable to the tropics. Palaeoenvironmental and landscape reconstructions can be satisfactory even with taxonomic determination limited to genus. Likewise, a large scope of archaeobotanical data can be obtained, especially related to wood use in domestic and ritual contexts, but also to other aspects such as site formation processes and indicators of people's mobility in the landscape (e.g., Scheel-Ybert 2014; Dotte-Sarout et al. 2015).

Future Directions

Since the 2000s, a great increase has been observed in the number of both anthracological publications and existing charcoal collections, as well as in their geographical spread. Even if anthracological research still remains much more widespread in Europe/Mediterranean and in temperate regions, it has firmly advanced in South America, Australia and the Pacific region, and Africa. Conversely, few studies have been developed in North and Central America and in Asia. A larger dissemination of anthracological studies, in both tropical and nontropical regions, is an important endeavor of the discipline.

The improvement and expansion of charcoal collections and online databases is an important step to fostering the development of the discipline and encouraging its new applications. Wood anatomical studies are extremely useful in helping charcoal identification, but the identification process is more straightforward when charcoal is directly compared to extant charred samples. Thus, charcoal comparative collections are essential to reliable charcoal identifications – especially in the tropics.

One of these possible new applications of anthracology has recently come to light in Brazil. Forest scientists have been committed to the development of extant charcoal identification. This approach seeks the recognition of species from fires of natural and anthropogenic origin and the controlling of charcoal production in order to reduce the illegal wood extraction from native biomes.

Dendroanthracology is another line of research that has experienced much growth. The multiplication of these studies and the establishment of stronger theoretical and methodological frames are under way. So is the application of dendroanthracometrical techniques to tropical regions, which is a great challenge. On the one hand, the huge biodiversity prevents the establishment of specific models. On the other hand, the rarity of growth rings compels to the development of protocols exclusively based in other anatomical features – such as rays or fibers. Yet this development will be a major contribution in view of the understanding of vegetation structure and cultural practices.

In general, the theoretical and methodological bases of Anthracology, as a discipline, have been largely established. Still many issues remain yet to be addressed. Key subjects are a better understanding of cultural practices and of taphonomic processes that might have engendered different charcoal assemblages. While the first topic depends on the development of ethnobotanical/ethnoanthracological/ethnoarchaeological studies, the second one calls for more experimental research.

Those are critical research challenges both in nontropical and in tropical areas. Still a larger investment in establishing theoretical and methodological premises specifically adapted to tropical regions is also key to the future of the discipline.

Anthropogenic Environments, Archaeology of

Rebecca M. Dean
University of Minnesota Morris, Morris, MN, USA

Introduction

The term "anthropogenic environment" suggests, in its etymology, an environment that is created by humans, but the archaeological study of anthropogenic environments is primarily concerned

with the coevolution of human communities and their landscapes, the dialectic between ecology and society.

As the intersection between culture and ecology, anthropogenic environments provide a critical record of past human impacts on the environment, an aspect of archaeology that is critical for contextualizing current environmental problems. From an ecological perspective, human modifications to the environment can be both positive and negative, leading to increases in biodiversity as well as decreases. The archaeology and anthropology of anthropogenic environments have led to the recognition of traditional landscape management practices as important to the development and maintenance of ecological diversity in many regions worldwide. Anthropogenic environments also preserve records of past societies; diet, subsistence practices, labor organization, social organization, settlement patterns, and beliefs are all part of the relationship between people and their environments and therefore leave some archaeological trace on the landscape.

Zooarchaeology, archaeobotany, and geoarchaeology are the methodological subfields most commonly used in the study of anthropogenic environments. These are the fields best suited to the study of human/environmental interactions as seen through the impacts human communities have had on animals, plants, and soils or landforms.

Definition

Anthropogenic environments are also called culturally modified environments or human-modified landscapes. Modifications of the environment, whether minor or profound, are ubiquitous wherever human communities are found. In the modern world, therefore, essentially all environments are anthropogenic, to the extent that they have been altered by human occupation. In practice, however, archaeologists usually define anthropogenic environments as those that show measurable changes in ecological dimensions, such as plant and animal diversity or soil fertility, that can be attributed to human modifications.

The tendency of Western societies to see the environment and human societies as categorically separate (the nature/culture dichotomy) makes anthropogenic environments difficult to define. The English language and Western philosophy define humans as distinct from their ecological context, but the study of anthropogenic environments demands a recognition of humans as part of the environment, one important component within the ecosystem. Anthropogenic environments are the result of the dialectic between human communities and their context, a physical manifestation of the enveloping web of relationships between humans, their landscape, and other animal and plant species.

The archaeological study of anthropogenic environments focuses on three common types of human interactions with the environment: impacts on plants, impacts on nonhuman animals, and the modification of soils or landforms.

The modification of soils or landforms can take many forms, often (and most spectacularly) related to agriculture, but certainly not limited to agricultural societies (Fig. 1). Terracing, irrigation, soil amelioration (including the creation of dark earth), damming, and other modifications of the landscape are frequently associated with the cultivation of domestic or wild plants but can have a strong effect on the composition and growth of all members of the local plant community, including weedy annuals and tree growth. The creation of roads, paths, fields, houses, burial mounds, or villages can also affect plant and animal species by changing water runoff patterns and soil compaction and creating edge effects that increase diversity. These deliberate modifications of the landscape have both intentional and unintended effects on species composition. Additionally, use of the landscape can have disastrous effects on soils and productivity, through salinization or erosion.

Human impacts on plant species and communities include domestication, transplantation, the extension of normal range (for either domestic or wild plants), cultivation of wild or semidomesticated plants, clear-cutting of forests, burning of forests or grasslands, and the preferential destruction or encouragement of certain species. Less

Anthropogenic Environments, Archaeology of, Fig. 1 A terraced agricultural landscape, along the Douro River, Portugal

direct, but often just as significant, are human-caused changes to habitats or growing conditions, whether or not such changes were intended to impact plant species. These include most of the modifications of soil and landforms mentioned above. For example, irrigation, soil amelioration, and terracing have a profound effect on plant growth, as can clearing vegetation for a field or trampling soil for a path. These effects can be wide-reaching and impact not just the specific species that may have been targeted (if any) but also weedy annuals that may take advantage of these anthropogenic niches. Agricultural systems, such as monocropping or multicropping, can also impact the diversity and density of regional plant communities (Fig. 2).

Anthropogenic Environments, Archaeology of, Fig. 2 Agave growing in rock mulch gathered from the desert floor, Arizona, USA

Similarly, human societies and communities impact animal species through domestication, transplantation (of wild or domestic animals), range extension, overhunting, and the targeting of particular age/sex classes of prey. Human impacts on plant species, like those discussed above, can also have a profound effect on animal communities, through changes to habitat and food supply. Burning is commonly used to increase the range and abundance of grazing animals, for example, but irrigation, terracing, and other modifications that lead to denser or more diverse plant cover can also increase the abundance and diversity of animal communities. Clear-cutting of forests, damming of rivers, and wide-scale pollution can also lead to the local extinction of some species. Livestock can also impact landforms and

plant communities through over-grazing, a common cause of erosion and changes in seed distribution and plant survivorship.

While anthropogenic environments are, in a sense, human "created," the relationship between people and their environments is more complex and nuanced than this implies. Anthropogenic environments are, in essence, contingent landscapes; landscapes reflect past histories of use and modification, and current uses and modifications are dependent on the choices made in previous generations. A fundamental recognition that all people live in contingent landscapes is fundamental for an understanding of modern environmental problems.

Historical Background

The history of the archaeological study of anthropogenic environments mirrors changes in popular conceptions of the environment and how it relates to human societies and also to the development of theoretical perspectives on the environment in the fields of ecology, anthropology, and geography, which have strongly influenced, and been influenced by, archaeology.

The Western concept of nature/culture dichotomy has roots as deep as ancient Greek philosophy and continues to be enshrined in popular and scholarly culture. The tendency for Western scientists and philosophers to see non-Western people as part of nature – a tendency fueled by the unwillingness of colonial powers to recognize the accomplishments of indigenous people and the land claims that went with them – initially made it difficult for Western archaeologists to recognize the extent of anthropogenic landscapes around the world.

Early understandings of human/environmental interactions in the social sciences often took the form of extreme determinism. As a backlash against these simplistic views, environmental arguments were avoided during the early development of archaeological theory. A culture's environmental setting was considered little more than an enabler or (more frequently) limiter of human behavior. After World War II, however, popular recognition of the environmental effects of human population growth, pollution, and consumption increased. Archaeologists working with ancient states were some of the first to apply this recognition to the past, with the documentation of human-created environmental disasters that led to abandonment of settlements or collapse of civilizations (e.g., Jacobsen and Adams 1958). While large-scale societies were considered to have significantly depleted their environments, the ecological impact of small-scale societies, whether positive or negative, was not widely studied (but see Day 1953).

The first ecologically inspired theoretical perspective to gain wide purchase within anthropology was Julian Steward's. His 1955 *Theory of Culture Change* was the foundation for the school of Cultural Ecology, which saw social and subsistence organizations as adaptations to the environment. Steward's work focused heavily on subsistence and the technological adaptations adopted to implement a particular subsistence regime within a particular environmental context. Although Steward's approach was far better suited to the study of small-scale societies than earlier approaches to human/environmental interactions, his primary focus was on the impact that the environment had on people, rather than on a recognition of the diversity of impacts people could have on the environment.

Popular and scientific understanding of the environment, and particularly environmental problems, was revolutionized by the 1962 publication of Rachel Carson's classic *Silent Spring*. Carson documented the degree to which the catastrophic effects of human actions could be both widespread and subtle. Overtly destructive actions, such as logging or strip-mining, were not the only environmental threats, nor could protecting national parks and wilderness from development solve the problems of invisible poisons in the air, soil, and water. Carson showed that urban, agricultural, and rural landscapes, as well as our own health, had to be protected from the effects of pollution. Population pressure, and the threat of population growth to the environment, was another important scientific and popular theme of the 1960s, with the publication of Paul

Ehrlich's (1968) best seller, *The Population Bomb*.

Although the focus of public discourse was on the destructive impacts of human actions on the environment, within anthropology and archaeology there was increasing recognition of the coevolutionary aspects of human/environment interactions. Anthropologists of the 1960s were strongly influenced by equilibrium models of ecosystems. In these models, disturbance – including positive and negative feedback from cultural or non-cultural sources – was thought to pull the ecosystem away from a "natural" vegetation regime. When disturbance ended or was minimized, the ecosystem would return to this "baseline environment." Under these models, small-scale communities could be seen as inherent environmentalists, living within the equilibrium of their environment. This was an idea supported by the work of Roy Rappaport (1968) who argued that complex cultural adaptations maintained ecological balance. Similarly, while Ehrlich (1968) had warned of the negative consequences of unchecked population growth, within archaeology, the late 1960s saw the emergence of models suggesting that population pressure drove social and technological change in human societies. The shift to Mesolithic/Archaic ways of life, the development of agriculture, and the rise of urbanization were all attributed, at least in part, to population growth (Boserup 1965; Binford 1968; Flannery 1969; Athens 1977).

Anthropological awareness of human impacts on the environment broadened as the issue gained increased public recognition. Vayda and Rappaport's (1968) seminal paper "Ecology, Cultural and Non-Cultural" became a critical theoretical underpinning of the study of human/environmental interactions and particularly anthropogenic environments. This interest moved beyond a focus on complex societies, as a growing interest in the origins and effects of agriculture and agricultural intensification led to a focus on the impact of small-scale farming societies on ecosystems (e.g., Netting 1968). Foraging societies were also recognized as having a significant impact on their environments at this time, with Martin and Wright's (1967) publication of *Pleistocene Extinctions: The Search for a Cause*, one of the first attempts to systematically explore the possibility that small-scale hunting and gathering societies may have caused wide-scale prey extinctions.

While Cultural Ecology remained the dominant theoretical perspective on human/environmental interactions through the 1970s, the 1970s and 1980s saw the diversification of theoretical approaches, particularly the development of Human Behavioral Ecology, which focuses on the use of optimality models for explaining human behavior (Winterhalder and Smith 2000). Optimality models have their base in ecology, particularly Charnov's (1976) "Optimal Foraging: The Marginal Value Theorem," but are also developed from rational choice models popular in economics. While classic works of Cultural Ecology sought to explain human behaviors as adaptations to maintain ecosystem balance, Human Behavioral Ecologists argued for short-term and self-serving behavior by individuals seeking to maximize individual fitness. Although the behaviors best suited to survival might involve conservation of local landscapes, Human Behavioral Ecology did not assume that such conservation was necessary or desirable to the actors involved. From the perspective of evolutionary theory, Human Behavioral Ecology is more defensible in its focus on individual fitness than Cultural Ecology, since the latter's theoretical approach can rely on an assumption of group selection. Human Behavioral Ecology, however, did not significantly improve archaeological understanding of anthropogenic environments, since the focus on individual actions meant that Human Behavioral Ecologists tended to see human impacts on the environment as inherently negative (or absent) rather than part of a feedback loop (as with Cultural Ecology) or as a dialectic with the local landscape that could be both positive and negative for environmental health.

The 1980s brought a better understanding of the dynamic relationship between human communities and their landscapes, as equilibrium models of ecosystem dynamics were abandoned in favor of non-equilibrium models that rejected the idea of "natural" baseline environment that was

maintained through a series of feedback loops. Instead, ecosystems were seen as highly dynamic, influx, and contingent, with disturbance part of the system, rather than inherently negative. Non-equilibrium models challenged the view of humans as either destroying the "natural" vegetation regime or adapting to an existing ecological balance. Rather, people were situated squarely within the ecosystem, as just one more source of dynamic and historical change.

The use of non-equilibrium models is most strongly associated with the development of Historical Ecology, which emerged in the last decade of the twentieth century (Balée 2006). Historical Ecology's focus on non-equilibrium models, and particularly the recognition of contingent landscape development, makes this the natural theoretical perspective for fully exploring the role that humans have played in shaping environments over millennia. Historical Ecology is particularly suited for the study of small-scale agricultural societies and the many subtle and profound ways that such societies manipulated their environment, creating whole landscapes shaped by human actions. Early works on the landscape management of small-scale agricultural societies, such as Posey's (1985) "Indigenous Management of Tropical Forest Ecosystems: The Case of the Kayapó Indians of the Brazilian Amazon," were instrumental in recognizing the scope of anthropogenic environments.

Throughout the 1990s, anthropological research continued to refute the idea that the indigenous people of any continent had failed to change their local and even regional landscapes. Influential articles, such as Redford's (1991) "The Ecologically Noble Savage" and Denevan's (1992) "The Pristine Myth," were published just before the UN Conference on the Environment and Development in Rio, which brought to the forefront the environmental problems of traditional and developing nations. The rejection of the view of small-scale societies as inherent conservationists was founded on strong ethnographic and archaeological data. Some of this data, however, had been present since the 1950s or earlier. The increasing acceptance of this perspective had as much to do with changing paradigms as with new data. The growth of postcolonial and indigenous archaeologies helped to refute older theoretical perspectives on small-scale societies that had deep roots in archaeology's colonial past.

Key Issues/Current Debates

The study of anthropogenic environments is tied to the increasing importance of applied archaeology as it relates to modern environmental policy and conservation efforts. An understanding of how people have changed their environments in the past can be used to improve modern environmental policy. This includes the use of archaeological and historical data to guide the reconstruction of damaged ecosystems as well as the use of archaeological knowledge of past technology (e.g., agricultural technology) to improve modern landscape modification practices.

The concept of environmental reconstruction assumes a "baseline environment" that can be reconstructed. As discussed above, however, current theoretical perspectives recognize the inherent dynamism of ecosystems. The focus on anthropogenic landscapes allows for a better understanding of the complexity of environmental reconstruction, a process that does not necessarily involve minimizing disturbance and human impact. If all environments are anthropogenic – and in fact many degraded modern environments are degraded from a healthy diversity that was created through human manipulation – then the purpose of reconstruction must be something other than to return the environment to a pre-manipulation state. Specific goals, such as increasing diversity or decreasing erosion, must be identified, and the recognition made that such goals may be best gained through active cultural manipulation of vegetation and landforms.

The archaeology of anthropogenic environments can provide data on the species of plants and animals present in past environments, the past landscape manipulations that created the environment, and the cultural behaviors that improved environmental health. Archaeologists are also increasingly applying lessons from past societies to help local communities improve quality of

human life as well as improve or protect environmental diversity. For example, archaeological studies of Amazonian dark earth (terra preta soils) may help protect the Amazon rainforest by reviving prehistoric soil amelioration practices that allow farmers to use the same plot of land for longer, rather than expanding into nearby forested regions when fields lose fertility (Lehmann et al. 2004).

International Perspectives

The understanding of anthropogenic environments has a peculiar history within the Americas, which makes their importance (politically, economically, and socially) far different from Eurasia or Africa. Concepts of the "ecologically noble savage," which only recognized European-style agriculture, architecture, and landscape modification as "cultural," were the result of blindness to the accomplishments of indigenous people and were also part of the colonial justification for land acquisition. When native land transformations, and the indigenous people themselves, were seen as "natural," then their land could be considered "unimproved." This was used as justification for European appropriation.

Although there is now a much greater understanding of the impact indigenous people had on the landscapes of the Americas, the colonial history of this topic, as well as the colonial history of archaeology itself in the Americas, continues to impact scientific and popular understanding of environmental transformations. The modern landscapes of the Americas are a part of the cultural patrimony of groups of people who were historically only a peripheral part of archaeological discussions.

Future Directions

Archaeologists interested in anthropogenic environments are increasingly engaged in applied research, both through engagement with environmental policy makers and through the application of archaeological knowledge to change or modify present behaviors that could harm the environment or human health. As the destruction of ecosystems intensifies and greater interest is paid to environmental problems, an understanding of past human/environment interactions will become more critical for understanding how environmental problems can be solved and predicted.

A

Anthropogenic Sediments and Soils: Geoarchaeology

Manuel Arroyo-Kalin
Institute of Archaeology, University College London, London, UK

Introduction

Archaeology has gradually but consistently increased its interest in the study of soils and sediments over the last decades. As a result of this emphasis, the discipline has not only sought to characterize the terrigenous matrix within which the great majority of archaeological materials are found but, increasingly, to also understand soils and sediments in their double dimension: as archives of archaeological and environmental data and as *sui generis* artifacts (Butzer 1982; Waters 1992; French 2003; Holliday 2004; Goldberg and Macphail 2006; Walkington 2010). This salience notwithstanding, a tendency to conflate the meaning of sediments and soils continues to exist within the discipline. In some cases, this owes much to the nature of archaeological findings and their context; artifacts are found in sediment deposits that have stratigraphy and which, generally speaking, are sufficiently close to the surface to be affected by soil-forming processes. Be that as it may, it is useful to draw a contrast between "anthropogenic sediments" and "anthropogenic soils" (and indeed between sediments and soils) because the distinction highlights different earthly processes that can affect the formation of this type of archaeological evidence. Put another way, both anthropogenic sediments and anthropogenic soils imply

terrigenous material with distinctive characteristics resulting from the strong and enduring influence of past human activity. However, each concept emphasizes a different aspect of the life history of the landscape, that demands the separate attention of archaeological research, especially the subdiscipline of geoarchaeology.

Definition

Sediment is non-lithified material made up, most of the time, of mineral particles of different composition, shape, and size. Sediment is subject to alteration through weathering and can be transported by different agents, which can select different particle sizes as a function of overall energy. Sediment is generally studied by archaeology in deposits that have stratigraphy: the composition of particles, their distribution in terms of size classes, and the sedimentary structures at various scales of observation both inform about the history of a deposit and provide crucial information about preservation factors (Goldberg and Berna 2010). Anthropogenic sediments are those sediments whose distinctive characteristics are a result of the strong and enduring influence of past human activity. Their geoarchaeological study focuses on their composition, history of deposition, and post-deposition alteration, taking into account the significant material effects of human agency. A more intuitive starting point is that most human activity takes place on land surfaces and that land surfaces are subjected to different actions that modify their characteristics over time. Modifications resulting from the activity of people produce a specific range of changes and inputs that lead to detectable differences when preserved: even fairly simple human activities can produce a variety of debris, e.g., charcoal, ash, bones, pottery, plaster, lithics, phytoliths, and slag; one might also consider here other human activities such as excavating, heaping, and winnowing of sediments for different purposes. The archaeological correlates of these inputs and activities are detected through specific material signatures that endure over time and alter the measurable properties of sediments. It is important to underscore that anthropogenic sediments do not only include sediments enriched by anthropic debris or depleted by associated chemical alteration. Unaltered sediments that have been relocated by humans (for instance, those used in platforms, agricultural raised fields, as well as sand or clay mined from quarries and transported to other locales), and sediments that have been modified by humans as raw materials for the manufacture of objects (e.g., clay deposits for making pottery, adobe, and mudbrick), among others, also deserve to be considered as anthropogenic sediments. Human impact on the stability of sedimentary deposits (for instance, through vegetation clearance and burning) are also known to contribute to higher mobility of sediments (e.g., via erosion), but the concept of anthropogenic sediments is probably best reserved for those sediments so mobilized that show the enduring and telltale material signatures of human activity, e.g., re-deposited anthropogenic sediments and soils.

A measure of the importance of distinguishing between anthropogenic sediments and anthropogenic soils is gained by examining what the notion of soil embodies and, consequently, how we can understand the notion of anthropogenic soils. Soil constitutes a complex and open system, a material continuum that drapes the entire planet. It is an assortment of organic and mineral material resulting from the interaction between geomorphological and biotic processes as they affect, and modify the properties of, surface sediments. Collectively, these processes are known as soil-forming or pedogenetic processes and lead to the formation of distinctively patterned layers known as soil horizons (Phillips and Lorz 2008). While key characteristics of soil horizons are determined by the parent material of soil, in other words by the actual composition of the sediments upon which soils have formed, the differences that can be observed between horizons are often the result of the decay, mixing, and depositional action of soil, the mobilization of non-consolidated or dissolved mineral and organic material through the existing pore structure (much of which results from the action of soil biota), and other forms of chemical modification. Horizontal variation in soil characteristics along a land form – a soil

catena – subsumes contrasts in parent material as well as variation in slope, drainage, vegetation cover, etc. Anthropogenic soils, in turn, are those whose formation and characteristics have been enduringly influenced by the material effects of human action. Their geoarchaeological study emphasizes an interpretation of the properties of soil horizons as a partial outcome of past human modification. Examples are as varied as they are intriguing: they include soils which were deliberately enhanced through the addition of materials in the past (often to increase fertility, including here compost heaps, home gardens, and agricultural fields) inasmuch as the mineral and even organic components are resistant to degradation; they also include soil horizons formed on human-transported or human-manufactured anthropogenic sediments (e.g., landforms created or altered by humans, including raised fields, soils formed on disturbed materials associated with mining); soils formed in situ on abandoned habitation areas; and soils whose surface horizon has been modified by topsoil disturbance and/or irrigation associated with different types of agriculture (e.g., slash and burn soils, paddy soils), among others (Limbrey 1975; Woods 2003; Dudal 2005).

Anthropogenic sediments and soils exist at variable spatial and temporal scales, from sand piles, pit fills, and compost heaps ephemerally accumulated in the vicinity of houses to entire landscapes blanketed by sediments dislodged by clearance and modified through millennia of continued agriculture. The foci of geoarchaeological studies of anthropogenic sediments involves, among others, establishing which sediments have been transported by humans deliberately (and wherefrom), which in situ sediments have been modified due to human activity (and how), and which sediments have been chosen to craft particular materials (wherefrom and how). The study of anthropogenic soils, on the other hand, includes how soil horizons' properties record the enduring influences of past populations (and to what extent the soil archive can be used to examine past land use), how these material signatures can be used to infer past human activity, and whether soils formed on old occupation deposits have been subsequently employed for cultivation, among others.

Historical Background and Current Debates

Archaeological research focused on anthropogenic inputs on soils and sediments trace their lineage back to Arrhenius' studies of phosphate enrichment in Sweden (Arrehenius 1929) and include geochemical prospection in a wide array of different contexts. The interpretation of modified properties as evidence of anthropogenic enrichment rests on the conceptual premise that humans concentrate metals and nonmetals, and develop other signatures in the sediment record (for instance, enhanced magnetism as a result of burning, changes in pH, etc.). Ethnographic and actualistic situations, in turn, document enrichment with phosphorus, carbon, calcium, potassium, magnesium, manganese, zinc, copper, and other elements associated with different settlement practices or activity areas (Woods 2003). These studies constitute a powerful tool to infer patterns in the use of space, especially when chemical properties are interpreted with the aid of micromorphological observations (Milek 2012). In this connection, compared to some pioneering research of the 1970s and 1980s (Eidt 1984, 1985), the application of micromorphological observations (Courty et al. 1989) has both greatly expanded the overall scope of this research and illustrated the remarkable heterogeneity that characterizes occupation deposits as archives of past human activity (Brochier 2002; Goldberg and Macphail 2006).

Approaches to the study of anthropogenic soils as archaeological entities owe much to studies of *plaggen* soils, the latter being deliberately enhanced farming soils resulting from applications of manured animal bedding made of heather, grasses, and peat by medieval farmers of the sandy lowlands of North-West Europe (Blume and Leinweber 2004). Examples are studies documenting the impact of *plaggen* cultivation on the landscape and research focused on determining new recipes for *plaggen* production (Simpson et al. 2005). Other examples of anthropogenic soils modified for agricultural purposes include soils modified by liming (Conry 1971) and *terra mulata* soils of the Amazon basin, modified by intensive in-field burning (Arroyo-Kalin

2012). In parallel, studies emphasizing the deliberate "making" of anthropogenic sediments include the construction of ash mounds of South India (Paddayya 2002), the making of Tell mudbrick (Rosen 1985) and New World adobe bricks (Goodman-Elgar 2008). Also important are studies devoted to the construction of mounds from more incidental materials, including earth and shells (Roosevelt 1991; Gaspar 1998; Villagran et al. 2011; Rostain 2012).

Worthy of note are examples of anthropogenic soils developed on abandoned archaeological sites, such as Amazonian Dark Earths (Arroyo-Kalin et al. 2009) and European Urban Dark Earth (Macphail 1983; Cammas 2004). Some of the more sophisticated geoarchaeological studies of these deposits focus on ascertaining the properties, mode of formation, spatial extent, and variability of anthropogenic soils, with a particular emphasis on how pedogenetic processes have been affected by past human action (Cremasci and Nicosia 2010). Further areas of research include the actual timing of anthropogenic soil formation (Arroyo-Kalin 2012) and the extent to which these soils, enriched with human occupation debris, can be said to have been used for cultivation (Devos et al. 2009). The latter is an important avenue for research in light of ethnoarchaeological and actualistic studies documenting within-settlement soil improvement (Schmidt 2013, in press), as well as sophisticated, experimentally-based, studies of the material signatures of past cultivation (Lewis 2012). A related line of enquiry focuses on the use of refuse and/or manure in broad areas around settlements, which has prompted important discussion in the archaeology of North-West Europe, the Mediterranean region, and Middle East (Wilkinson 1989; Bintliff et al. 1990; Guttmann 2005).

Techniques employed in the study of anthropogenic sediments and soils are, for the most part, those deployed in other environmental archaeology investigations (Rapp and Hill 1998; O'Connor and Evans 1999; Goldberg and Macphail 2006): a combination between quantifying inclusions and fossil remains, measuring physical and chemical properties of terrigenous material, and studying undisturbed samples microscopically – all within an understanding of processes of landscape evolution. A key methodological issue, however, is the need to establish adequate baselines to assess anthropogenic modification. While human activity can be linked to higher phosphorous, calcium carbonate, carbon, as well as changing particle size classes and enhanced magnetism, it is not straightforward to successfully establish the extent of enrichment or depletion of soils and sediments in absolute terms. One approach is to use maps to compare relative abundance of selected parameters. Another is to employ a "background" for comparison. The extent to which this "background" is equivalent to "natural" conditions depends on the particular features of different regions: in some areas of the world agricultural modification of large expanses makes it next to impossible to detect parts of the landscape that are comparable to archaeological situations and which have not seen major impact by humans (Sanders in Turner and Sanders 1992). In other parts of the world, "backgrounds" can and should be sought because their study permits understanding local processes and situating anthropogenic modification in the specific context of local sediment dynamics and soil forming processes (Arroyo-Kalin et al. 2009). In this connection, some crucial considerations are to study "background profiles" rather than simply "background topsoil samples" (in order to compare to the profiles, rather than surface samples, of archaeological interest); ideally, to locate study profiles on the same landform as archaeological exemplars; and, importantly, to take into consideration the position in the soil catena or palaeocatena (French 2003).

Future Directions

The fundamental common ground between the study of anthropogenic sediments and soils is that both bear distinctive characteristics which can be traced back to human action. These characteristics are enduring, such that, on the one hand, they can be studied as material signatures of past human activity and landscape transformation and, on the other, they can affect the

properties of anthropogenic sediments or anthropogenic soils, rendering substrates that have become enriched, depleted, polluted, or otherwise transformed as a result of human agency. Given the ubiquity of human modification of the landscape throughout the Holocene – in many cases an integral consequence of the widespread adoption of agricultural livelihoods over millennia – geoarchaeological studies of anthropogenic soils and sediments constitute a developing and ever more important research program. It is increasingly realized that questions such as "What was the human impact on past environment?" can in many contexts oversimplify the issues at stake, namely, that the legacy effects of past human inhabitation constitute an important source of landscape variability which subsequent inhabitants had to both confront and creatively engage with (Stahl 1996). Put another way, in many cases, and via the enduring effects of manipulating environmental affordances, human populations have played the role of a keystone-species (Balée 2006), both in the flux of ecological interactions and as part of long-term processes of change that have modified the actual properties of the landscape.

Anthropological Genetics

Toomas Kivisild
Department of Archaeology, University of Cambridge, Cambridge, UK

Introduction and Historical Background

Anthropological genetics is a study of the history of human genetic variation in the past and present. It applies methods and theory of evolutionary biology and population genetics on genetic data from human populations to address questions drawn from biological (physical) anthropology. In the broadest sense, anthropological genetic research covers a wide range of questions:

"What is it in our genes that makes us human?" "How does human genetic variation relate to that of other animals and great apes in particular?" "What is the genetic basis of normal (non-disease related) variation of phenotypic traits?" "When and how did regional differences in allele frequencies arise among populations?" "How to obtain and interpret evidence for natural selection in human evolutionary history?" "What inferences about demographic histories, spread of languages, and material culture can we make from genetic data?" Anthropological genetics overlaps with other research fields interested in variation among humans at molecular level, such as the following:

> "Molecular anthropology": In which any molecular evidence, including DNA, lipids, and proteins, is used to understand the extent and nature of human variation.
>
> "Forensic Anthropology": Its overlap with genetic anthropology lies in individual and population level identities as well as the study of phenotype/genotype relationships.
>
> "Archaeogenetics": More restricted to the study of human past (than present) with methods of molecular genetics.
>
> "Gene geography": Perhaps the least widely used of these parallel terms to characterize more specifically the study of spatial variation of allelic variants of genes.

Historically, anthropological genetics can trace back its roots to the serological studies of the early twentieth century which were the first to explore the distribution of the now "classical" genetic markers in human blood samples collected from across the world. The work of Dungern and Hirszfeld in 1910–11 on families of the academic staff of Heidelberg University showed that simple Mendelian rules of inheritance apply also on human ABO blood group data. During World War I, Ludwik and Hanka Herszfeld collected ABO blood group and hair color data from soldiers of different ethnic backgrounds. Their work provided the first insights into patterns of geographic variation of human genetic diversity. It should be kept in mind when reading papers from that time, however, that in the anthropological genetic studies published before World War II, the geographic patterns in human serological data were largely interpreted within the framework of racial categories. These early genetic studies tried but failed to find conclusive support to typological concepts of human variation as each marker system produced a different set of "races." After World War II, more blood group systems were described and the work on the characterization of their frequencies in human populations continued. The global frequency distributions of hundreds of classical markers were summarized and systematically analyzed in the works of Luigi Luca Cavalli-Sforza and Arthur Mourant. *The History and Geography of Human Genes* (Cavalli-Sforza et al. 1994) presented the analyses of synthetic maps of variation of many classical markers becoming a standard reference on human genetic variation. These synthetic maps, based on principal component analyses (PCA), have been for many later studies the starting blocks for hypothesis testing and interpretations of the correlation between genetic maps and distribution of languages and archaeological sites.

Implementation of polymerase chain reaction (PCR) technology in population genetic studies in the 1980s started a new era in anthropological genetics as it became easier and affordable to study the sequences of short targeted regions of DNA in large numbers of human samples. PCR requires only small quantities of starting DNA per sample, and therefore noninvasive biological source material, such as hair and buccal swabs, became accessible methods for collecting samples in anthropological fieldwork. This democratization of anthropological genetics meant that many labs started to carry out genetic work on humans leading to increasing volumes of data published on increasingly larger number of human populations. This, in turn, created the need for new analytical tools to interpret the variations observed in these short stretches of targeted sequence among human groups. Wider sampling of human populations brought up new questions about research ethics that needed to be resolved: questions about ethical use of DNA information with individual consent and questions about ethical use and interpretation of genetic data sampled from minority ethnic groups.

Dating Human Genetic Variation: Interpretations of Coalescent Trees of Individual Loci

PCR-based analysis of sequence variation in mtDNA and non-recombining regions of Y chromosome became particularly popular foci in anthropological genetic research in the 1990s given the sex-specific inheritance of these loci and lack of recombination. These features rendered mtDNA and Y chromosome suitable for drawing phylogenetic trees to describe relationships among multiple individual sequences. Phylogenetic trees drawn from these two uniparentally inherited loci provided the opportunity to explore genealogical relationships among individuals drawn from a range of geographic locations via an approach called phylogeography by John Avise. By knowing the rate at which mutations occur, one can estimate time to the most recent common ancestors (TMRCAs) of mtDNA or Y chromosome sequence types (haplotypes), study the time depth of local and interregional scales of variation in the groups of haplotypes (haplogroups) related by common descent, and make phylogeographic inferences about the source areas and dispersal times of the carriers of the haplogroups.

The most recent common ancestors of all mtDNA and Y chromosome lineages alive today have been labelled as "mitochondrial Eve" and "Y chromosomal Adam," respectively. Although technically these terms refer to mathematical reconstructions of sequences that were likely to exist in real human bodies at some point in the past, they do not suggest that Adam and Eve were, in Biblical sense, the only human beings living at that time. Because of the stochasticity of lineage survival and extinction in finite-size populations, the age of TMRCAs of different loci can be vastly different, and indeed mitochondrial Eve and Y chromosomal Adam have been estimated to have lived thousands of generations apart (Fig. 1). Because the time to TMRCA is primarily determined by the effective population size of the locus – which can vary due to uniparental versus biparental inheritance, sex-specific processes, and natural selection – the time estimates of Eve and Adam do not necessarily reflect anything unusual happening to human populations at the time when they lived. The TMRCA dates of individual loci cannot, for example, be interpreted as genetic estimates of a speciation event, i.e., when a non-human mother (or a father) gave birth to (fathered) a human child, neither do they necessarily mean that human populations had unusually low number (a bottleneck) of females or males at the time when mitochondrial and Y chromosomal trees coalesce, respectively. The fact, however, that genetic variation in mtDNA, Y chromosome, and, in fact, most autosomal loci follows consistently a pattern whereby variation in non-African populations is a subset of genetic variation observed in Africa suggests that humans originated in Africa and from there colonized the world only recently.

Population Histories and Admixture Events Inferred from Whole-Genome Sequences of Modern and Ancient Populations

High-throughput sequencing methods revolutionized the study of ancient DNA in the first two decades of the twenty-first century. Anthropological genetics has become a more model-based and genome-scale study of variation in human populations. The shift from analyses of single-locus systems, such as mtDNA and Y chromosome, to whole genomes has allowed anthropological genetics to make interpretations about the history of populations with more vigor and power. An example of a paradigmatic change in our interpretation of human evolutionary history concerns the debate over archaic introgression. Studies of mtDNA and Y chromosome variation, relying on tens of thousands of individuals, were unable to detect Neanderthal admixture that we now know exists in the genomes of all non-African populations at the level of ~1–2% (Green et al. 2010; Reich et al. 2010). The ancient genomes of Neanderthals and Denisovans have allowed us to reconstruct the human population histories in the last half million years and to detect a number of introgression events (Kuhlwilm et al. 2016; Posth et al. 2017; Prufer et al. 2017) between the "archaic" and "modern" humans

Anthropological Genetics, Fig. 1 The most recent common ancestor (TMRCA) dates of autosomal genes are (about four times) older than Y chromosome and mtDNA TMRCAs because (four times) more autosomal gene copies are passed on by parents to offspring each generation. Because of the large effective population size (indicated by the width of the grey "population" background at the top of the graph) of their ancestral species, human and chimpanzee autosomal genes coalesce way earlier (at 13 MY on average (Prufer et al. 2017)) than the estimated species split (~7 MYA (Scally et al. 2012)). MY, million years; KY, thousands of years

(Fig. 2). Not all chromosomes and genes carry equal load of Neanderthal-related ancestry, and populations vary also qualitatively by the content of haplotypes that are ascribable to archaic introgression. Therefore it is not surprising that some individual loci do not show any evidence of introgression. Most Neanderthal- and Denisovan-derived haplotypes that are found in human populations occur at low frequency, while in some rare cases, called adaptive introgression, the archaic haplotype may have reached high frequency in some human populations as a result of positive selection. One such example is the *EPAS1* haplotype in high-altitude adapted Tibetans (Huerta-Sanchez et al. 2014).

Another illustration of how genome-scale ancient DNA evidence has changed the interpretations of the genetic history of human populations is the debate about the extent of genetic continuity and contribution of hunter-gatherers and Neolithic farmers to present-day populations of Europe. Two basic models had been at the core of this historic debate: one emphasizing the cultural diffusion of ideas of farming (Fig. 3d) and the other demic diffusion of the farmers themselves across Europe (Fig. 3a). Cultural diffusion model assumed substantial continuity of the genes of Mesolithic populations, while demic diffusion model proposed that present-day genetic variation in Europe reflects primarily that of the Anatolian farmers with some minor contributions from local hunter-gatherer populations. The map of the first PC of classical genetic markers in Europe (Fig. 3b) was interpreted as the primary genetic evidence in support of the demic diffusion model. The southeast/northwest orientation of the first component has been explained as the reflection of the "wave of advance" of Europe's first farmer dispersal starting from Anatolia. According to this view, the farmers with their advanced economy were able to reproduce more than hunter-gatherer populations, and as their population sizes grew, their territories expanded. As they expanded they mixed on their way with hunter-gatherer populations of smaller group sizes which eventually left behind a pattern of decreasing farmer contributions on the southeast to northwest axis. However, clines can also be generated under models, such as isolation by distance (Fig. 3c),

Anthropological Genetics, Fig. 2 Simplified model of human origins and archaic introgression

that do not assume differences in population densities or dispersal of one group into the territory of another.

Phylogeographic studies based on mtDNA and Y chromosome variation in the late 1990s argued for a substantial degree of continuity of European hunter-gatherer haplotypes and suggested that the southeast to northwest cline in the first two principal components of classical markers as well as the frequency distribution of some mtDNA and Y chromosome haplogroups reflected a sum over several gene flow episodes from the Late Pleistocene to the Neolithic. More than 80% of modern European genetic variation was estimated to reflect continuity since Mesolithic. Ancient DNA studies have now revealed that a number of major population turnovers occurred in the Late Pleistocene and Early Holocene Europe (Posth et al. 2016) and that major changes in genetic composition of European populations continued to occur not only at the start of the Neolithic but also later at the end of the Neolithic and Early Bronze Age (Fig. 3e) (Brandt et al. 2013; Haak et al. 2015). Although a large proportion of present-day genetic variation in Europe derives from the Anatolian farmers, their genetic contribution to modern populations follows a south to north gradient (Fig. 3f) which is orthogonal to the southeast to northwest pattern (Fig. 3b) revealed by the classical markers (Lazaridis et al. 2014). The highest prevalence of genetic ancestry of the early farmers has been maintained in Greeks, Sardinians, and Basques even though the latter speak a non-Indo-European language that has been long considered to reflect the continuity of Europe's hunter-gatherers. These analyses of ancient genomes have shown that genetic landscape has changed repeatedly and to a substantial degree in

Anthropological Genetics, Fig. 3 Models explaining genetic structure in Europe. (**a**) The model of demic diffusion by means of wave of advance (Cavalli-Sforza et al. 1994). (**b**) The first principal component (PC1) map displaying the main pattern of genetics in Europe. PC1 explains 30% of the total genetic variation in a set of 91 classical markers (Cavalli-Sforza and Minch 1997) and only 0.30% when using >500,000 SNPs across the genome (Novembre et al. 2008). (**c**) Isolation by distance model. (**d**) Cultural diffusion model. (**e**) Changes in mtDNA haplogroup composition in ancient Central German samples (Brandt et al. 2013). (**f**) Estimates of the three major autosomal ancestry components in European populations based on ancient DNA analyses (Haak et al. 2015) https://www.eupedia.com/europe/autosomal_maps_dodecad.shtml#Neolithic_farmers

the population history of Europe, more so than portrayed by the dichotomy of wave of advance and cultural diffusion models. When considering the changes in patterns of genetic diversity over time, they "mirror migrations and culture" (Gunther and Jakobsson 2016) rather than just geography (Novembre et al. 2008), and therefore accurate reconstructions of the demographic history of past populations just from the patterns of genetic variation observed in modern populations may not be feasible.

Human Origins and Uniqueness

Comparisons of genetic data between species can inform us how different they are, how many changes, and in which genes have occurred over the course of millions of years since their common ancestor. Leaving aside structural differences, insertions, and deletions, human and chimpanzee genomes differ on average in 12 per every 1,000 base pairs, with a total of about 40 million differences spread across the genomes. While anthropological genetic studies have resolved the debate about which nonhuman primate is the closest relative to humans conclusively in favor of chimpanzee, they have also revealed that in 15% of the genes, humans are more closely related to gorilla because of the process called incomplete lineage sorting (ILS) (Scally and Durbin 2012). The time it takes for two species to become completely "sorted" so that all individual gene trees would match the species tree depends on the effective population size of the species during and after the split. It has been estimated that the effective population size of our ancestral great ape species may have been an order of magnitude as high as the long-term effective population size of human populations in the last couple of million years (Fig. 4).

Humans differ from great apes in more than a few hundred morphological, physiological, and behavioral characters (Varki and Altheide 2005), such as bipedality, the ability to run long distances, loss of body hair, language, as well as millions of genetic differences in our genome. Although both phenotypic and genetic differences have been increasingly well identified and catalogued in recent anthropological genetic research, we still have relatively little knowledge about which particular genetic changes map to which phenotypic traits and which evolved under strong influence of natural selection in making our ancestors behave and look like human. Using more distant outgroups, such as the orangutan or macaque genomes, it is possible to distinguish between the mutations that occurred on human lineage from those that occurred in the ancestors of modern chimpanzees. However, it

Anthropological Genetics, Fig. 4 Incomplete lineage sorting in great apes. *H* Human, *B* Bonobo, *C* Chimpanzee, *G* Gorilla, *O* Orangutan

has been notoriously challenging to define which of the 20 million or so changes that have occurred in the hominin lineage, i.e., between present-day humans and the common ancestor of humans and chimpanzees, are the ones which have caused the key differences in human brain development, cognitive abilities, locomotion, and appearances. Multispecies comparisons, experiments on human cell lines, scans of protein coding and regulatory regions for the level of their phylogenetic conservation, comparative analyses of tissue-specific expression, and disease association of individual variants have been used as methods to reveal genomic regions where changes are most likely to cause functional and phenotypically detectable differences between the species. Approximately 3,000 human genes have been shown to be intolerant to the loss of one of the two alleles (Bartha et al. 2018). Many of these essential genes are highly conserved and define components of basic cellular processes that if modified will almost certainly lead to fatality or reduced fitness and therefore are unlikely to include changes that converted ancestral apelike phenotypes to human. Only a relatively small number of candidate loci of human uniqueness have been thoroughly characterized for their biological effect on the development of cells and tissues in model organisms so far. Significant progress has been made, for example, in revealing the developmental mechanisms through which mutations in the human lineage have changed cellular and molecular reorganization of neural circuits of our brains (Fig. 5).

For the anthropological study of genetic changes that make us human, only a small number of DNA samples, at the extreme case only one individual sample per species, can be used to reveal most of the species-level differences with other great apes. Any set of human samples would equally well serve this purpose as we expect the genetic changes that define us as a species to be fixed in all human populations. Even if we were to include Neanderthals to our sampling, we would get highly similar list of genetic differences with chimpanzee and gorilla given the shortness of the list of fixed genetic and phenotypic differences between modern humans and Neanderthals (Green et al. 2010). However, when examining this list of genetic changes that are fixed in modern humans, but in ancestral state in archaic humans, sample size becomes an important factor as the split between the "archaic" and "modern" populations (whether we can call it "speciation" is debatable) happened very recently and variation in majority of genes has not been sorted yet. Neanderthal and Denisovan introgression into non-African populations (Fig. 2) is another complicating factor that reduces the number of sorted differences between the groups. However, even when considering just Africans, only a very small proportion of genetic loci, only 87 protein coding genes out of ~20,000 (Prufer et al. 2014), in our genome include sites where all Africans are fixed for the derived allele, while Neanderthals and Denisovans carry the ancestral allele.

One of the central debates in anthropological genetics has concerned the dates of speciation events. How do hominin fossils relate to species split and gene divergence dates estimated from the genetic data? The date estimates assigned to splits on any gene or species tree depend on the mutation rate being used. Fossils with known dates and well-understood relationship with hominins and living great ape species are often used for mutation rate calibration. However, applying such phylogenetic rate estimates on taxa that separated millions of years ago can, however, be problematic as it relies on assumption that mutation rates and generation times have not changed significantly over time. Alternatively, one can estimate the mutation rate directly from human pedigrees. Phylogenetic rate calibrations yield ~2x faster rate estimates than the pedigree method, suggesting that rate variation across taxa cannot be ignored and when considering phylogenetic splits in the last 1 million years, slower pedigree rate appears to be more suitable for dating splits of archaic and modern human populations and relevant gene divergence dates (Scally and Durbin 2012).

In cases of large ancestral effective population sizes and/or permeability of species barriers to gene flow (introgressions), ILS can be the norm rather than exception, and the split dates of individual genes can substantially predate the date of

Anthropological Genetics, Fig. 5 Examples of genetic changes associated with human uniqueness that have been studied in mouse model. (Adapted from (Jobling et al. 2013; Sousa et al. 2017)). *H.s.* human, *P. t.* chimpanzee

the separation of the species under neutral model. But the differences between gene trees and species trees can be furthermore made more emphatic by natural selection. For example, haplotypes that define A and B alleles of the ABO blood system and haplotypes in the HLA locus on chromosome 6 responsible for immune response have local coalescent times in humans older than 10 million years. Variation in these loci has been maintained by balancing selection. In contrast, variation in genes that have been subject to directional positive selection can be significantly reduced in comparison with the genome average. While some of the genetic changes defining human unique traits may have evolved neutrally and become fixed in hominin lineage by random genetic drift, those that were subject to positive selection may be recognizable by their "extended lineage sorting" (Peyregne et al. 2017) and young coalescent times.

The oldest remains of anatomically fully modern humans uncovered so far come from East Africa and date to ~200 kya, while some of the anatomically modern features of the cranium appear already in a 315 kya Jebel Irhoud fossil from Morocco (Hublin et al. 2017). As the evidence for long distance trade, art, and symbolic thinking is more recent, it has been argued that behavioral modernity may have appeared later (Klein 2002) being driven by genetic switch which allowed our ancestors to go through a categorical behavioral change. It has been argued that this genetic change may have enabled spoken language, art, and symbolic thinking which allowed human populations successfully to expand out of Africa and colonize the world. Anthropological genetic studies have searched thousands of whole genome sequences for indication of such genetic change that would have left behind a signal of a selective sweep and have found no support for the model that would reduce the complexity of human behavior to one or few genetic changes. On average human genes have a coalescent date older than 1MYA (Fig. 6), and none of the genes in our genome has the most recent common ancestor younger than 100 kya to fit the predictions of Klein's model (Mallick et al. 2016). In fact, the coalescent dates of overwhelming majority of human genes are older than the split date of human and Neanderthal lineages which means that most genetic changes that make us humans (in comparison to other great apes) were indeed shared with archaic humans. The coalescent dates of only a fraction of 0.28% of short 50-kb windows in our genome postdate the separation of archaic and modern humans which makes the case of complete sorting and separation of "modern" versus "archaic" haplotypes a rare exception rather than a rule. Interestingly, amylase gene cluster represents one of such exceptional cases of an early selective sweep after the split of humans from Neanderthals which led to the fixation of multiple copies of salivary amylase genes in place of a single copy in the ancestral population of modern humans (Inchley et al. 2016; Lazaridis et al. 2014).

Anthropological Concept of Race and Genetic Ancestry

Anthropological genetic studies often use the term "genetic ancestry" to refer to patterns of genetic variation observed within and among populations. At the surface, given that the frequency distribution of individual ancestry components tends to be correlated with geography, it would be tempting to associate the genetic ancestry with the nineteenth century anthropological concept of race. And some authors have indeed tried to use genetic evidence in support of claims for the existence of discrete races within our species. However, there are several reasons why genetic evidence does not support the concept of race and why a clear distinction should be made between "genetic ancestry" and "race."

While we share remarkably high levels of sequence identity with our closest relatives,

Anthropological Genetics, Fig. 6 Distribution of autosomal TMRCA dates in humans. The plot shows the frequency distribution of dates estimated for 10kbp regions as TMRCAs at which all (100%) chromosome pairs in a sample of 24 African and 8 non-African genomes have coalesced. (Adapted from Extended data Fig. 7b (Mallick et al. 2016))

chimpanzees and gorillas, the tens of millions of differences that are sparsely spread across the genomes as fixed differences at the species level guarantee that species identification can be achieved unambiguously. Beyond that comfort zone, it is far more challenging to interpret the precise meaning of subgroups, particularly within human species, that can be identified with the use of DNA evidence. Individual genetic markers, as revealed already by the blood group studies of the first half of the twentieth century, can give rise to different frequency patterns across the geographic space that human populations inhabit today. In the absence of obvious barriers, such as oceans or mountain ranges, genetic differences tend to increase gradually over geographic space following the pattern predicted by the "isolation-by-distance" model (Fig. 3c) according to which most individuals mate and leave offspring near to their birthplace. If human populations were or had once been structured by anthropological races, the genetic patterns of individual genetic markers would be expected to converge toward the same underlying distribution. However, only a minor part of genetic variation, less than 15%, can be attributed to differences among geographically distinct groups, while the greater part of the variation is within populations.

On average, individual genomes determined from a wide range of human populations carry less than one difference of substitutional type per 1,000 base pairs. Such a low level of differentiation is compatible with a model of recent common origins of all human populations. A large proportion of these differences occur at sites that are called common variants. These are SNPs with minor allele frequency higher than 5%. Majority of common SNPs are shared not only among local neighboring populations but also globally among continental population groups. Because anthropological concept of race emphasized the existence, in the past, of pure racial populations, it also would have predicted that a large proportion of common variants should be continent specific. Available empirical evidence from thousands of genomes has shown that this is not the case. Most variants that are specific to a local population or continental region are rare, while most common variants are shared. There are indeed only a small number of variants that are at the same time common and highly differentiated to the extent that one allele is nearly fixed at 100% frequency in one continental area and the other allele near to fixation in another, e.g., in *SLC24A5* and *EDAR* genes. Apart from these exceptional cases where the knowledge of individual's continent of origin allows us to predict their genotype in the given genetic locus, overwhelming majority of variants in our genome do not follow this pattern.

The accuracy of identification depends on the number of genetic markers being used. Only a few tens of unlinked, randomly chosen common SNP markers would be needed to yield random match probabilities that are low enough for individual identification. However small the allele frequency differences are between human continental or regional groups, these differences can be employed in the calculation of probabilities of group membership, or in other words, for estimating genetic ancestry of individuals. Few thousands of common SNPs are required to confidently assign individual's genetic ancestry to a continent, while hundreds of thousands of SNPs are needed to discern patterns within genetically homogenous continental regions such as Europe. Predictions of individual's birthplace from genetic data via methods such as principal components analysis (PCA) yield meaningful results with precision up to a few hundred kilometers only when all parents and grandparents of the individual come from the same geographic region. However, not all our great-great-ancestors were necessarily born in the same place, and therefore the ancestry prediction provided by the analyses of thousands of common SNPs will necessarily inform us about the average of many ancestors.

Although methods for identification and quantification of admixture at the level of individual genomes have been developed, these, again, estimate the average contribution of multiple ancestors derived from a similar "ancestry" background rather than enabling us to be quite specific about any of our genealogical or distant ancestors at individual level. Many such algorithms are

designed to identify genetic structure in populations in the form of discrete ancestry components which does not mean that at any given time such unadmixed populations ever existed (Weiss and Long 2009). Because of the exponentially increasing number of genealogical ancestors we have when looking back to the past, the smaller and smaller the genetic contribution of each one of them becomes and hence the more and more "shared" our ancestry becomes rather than stemming from a single or a few clearly identifiable "genetic homelands" (Jobling et al. 2016).

Most common genetic markers are "old" and shared by a wide range of populations. In contrast, rare variants, i.e., those that occur in a population at frequency below 1%, are typically "young" and specific to one or few neighboring populations. Genome-wide analysis of a large number of rare variants can serve as population-barcoding for detection of regional substructure of populations at finer level (Genomes Project et al. 2015). In sum, both common and rare variants can be effectively used for predicting average birthplace of the group of genetic ancestors one has, yet the opposite, predicting genotype from birthplace cannot be achieved as variants that are common are shared, while with any rare variant, there is a very small chance that any individual carries the derived genotype. This means that no single gene or genetic variant conveys sufficient information about an individual ancestry for meaningful prediction of the allelic states of other SNPs or phenotypes. This type of distribution of information embedded within rare and common variants supports the recent out-of-Africa model and is not consistent with the long-term separation of human races under the anthropological concept of race which ascribed specific phenotypic, behavioral, and cultural differences to fixed genetic differences among the original, pure, races.

Phenotypic differences among human populations are often said to be skin-deep, and there is some truth in this claim in more than one sense. Firstly, most genetic variations are shared among populations, and there are only a few examples of functional genes that show high levels of allele frequency differentiation among populations. But, secondly, the few genes that show high levels of differentiation include those determining pigmentation of skin, hair, and eye color, and some other skin-expressed traits, such as hair thickness and curliness. Besides very small genetic differentiation and virtual lack of fixed genetic differences, most phenotypic variations seen among human populations are polygenic and based on a large number of shared common variants, each with small effect size.

Ethical Aspects of the Study of Indigenous Populations

Anthropological studies by the very definition have been interested in variation within and among human populations. Introduction of methods of genetics to anthropology has helped to resolve many questions about the extent and nature of relatedness between human populations, but it has also brought on the table new questions of ethical nature related to the ownership and patent rights of research outcomes and vulnerability for discrimination of populations whose DNA is examined. Ethnic minority groups are called "vulnerable" in situations where genetic research can have a potential of causing individuals from these groups, whether they have been directly sampled for the study or not, any economic and/or political disadvantage. Although overwhelming majority of genetic studies has clearly rejected the anthropological concept of human races, we cannot deny that racism nevertheless has continued to exist as a social construct in human societies. If a genetic study would reveal, for example, high incidence of a disease-associated mutation in a vulnerable group, such findings, if mishandled, could potentially lead to discrimination, e.g., by employers or insurance companies, against individuals from such communities, and therefore special care has to be taken when studying and interpreting genetic data from indigenous populations or minor ethnic groups.

One of the key issues with any genetic study is the sampling strategy – which groups and which

individuals should be included in a study. Major criticisms have been made from the grounds of ethics against projects sampling indigenous populations, such as the human genome diversity project (HGDP). The criticisms made have been about the controversies in the attempts of such projects to define and sample "pure" ethnic groups by avoiding sampling of populations with large degree of recent admixture. Ethical issues have also been raised against "biological imperialism" which refers, for example, to a case of patenting a cell line generated from the blood sample of a Papua New Guinea highlander from the Hagahai ethnic group by HGDP; potential use of genetic data in discrimination against the vulnerable groups; and the issues surrounding the cross-cultural concept of consent in cases where DNA of indigenous people can be used to undermine their own narratives of their origins and identity (Marks 2012).

While research on topics of anthropological genetics that are related to human origins and uniqueness does not necessarily require sampling of all populations of the world, there are some important areas of anthropological research where the inclusion of a wide range of indigenous populations has been essential for characterizing genetic diversity in our species in an unbiased way. These are questions about peopling of continental regions, including but not restricted to Americas and Australia, inferences of human dispersals, demographic bottlenecks and founder events in the past, and study of adaptational processes within our species.

Antioch, Apamea, and the Tetrapolis, Archaeology of

Andrea De Giorgi
Department of Classics, Florida State University, Tallahassee, FL, USA

Introduction/Definition

Seleukos Nikator is traditionally referred to as the founder of a constellation of colonies in the Syrian region and in particular of the *Tetrapolis*, a consortium of four sister cities that occupied first millennium BCE settlements: two inland foci (Antioch and Apamea) and two seaports (Laodikeia and Seleukeia in Pieria). Altogether, these foundations were essential in stamping Seleucid hegemony over Syria in light of the overall peaceful settlement with Ptolemy Soter, who in turn seized most of Phoenicia after the fall of Antigonos Monophthalmos. By this rationale, the *Tetrapoleis* created a web of urban foci that firmly secured the Orontes Valley and the coastline in Seleucid hands, thereby curbing expansion ambitions of the Ptolemies. We can safely infer that this ambitious plan of geopolitics was brought to completion in fairly rapid terms during the last years of the fourth century BCE, following the foundation of the new capital at Seleukeia on the Tigris, Seleukos' assumption of kingship, and Antigonos' defeat at Ipsos. As regards the agencies behind these foundations, the Macedonians, Athenians, Argives, and Syrians who figured so prominent in the ranks of the Seleucid legions in the campaigns between 306 and 300 BCE may have served in the initial construction of the *Tetrapolis* as well as in a series of equally ambitious urban achievements, many of which carried dynastic denominations.

Key Issues/Current Debates

In chronological order, Seleukeia in Pieria (Samandağ, Turkey) deserves primacy. It was the first foundation among the *Tetrapolis*, and

what is more, in Seleukos' plans, it was to become the next capital as well as his final resting place. Hence, in the aftermath of his key victory against Antigonos in 301 BCE, he offered sacrifices to Zeus on Mt. Kassios and shortly thereafter founded the city at a site seven miles north of the Orontes' delta, near modern Samandağ. Bearing witness to the ebb and flow between Seleucid and Ptolemaic rule in the region, Seleukeia throve as a hub of commerce, in particular, during the days of Pompey the Great. Later, under the mandate of the Flavian emperors, the city was inserted in the grand scheme of militarization of the Orontes basin. A new harbor was built, and along with it came a vast program of canals and diversion of waters to ease the navigability of the Orontes and prevent the silting of the harbor itself. Furthermore, Seleukeia became home of the *Classis Syriaca* and of detachments from the fleets at Misenum and Ravenna, as attested by a rich corpus of funerary inscriptions. All in all, the eastern campaigns of the second and third centuries CE fully harnessed the resources of Seleukeia's harbor. With the tetrarchic era, however, the harbor's role began to dwindle, a process accelerated by the rise of new hubs at Tyre and Antarados further south along the Syrian coast. That the city's abandonment may have started at this time is a cogent hypothesis. All the same Isaurian raids, the early sixth century's catastrophic earthquakes, and finally the Sasanian king Khusro's invasion brought city life to a halt; aside from the names of its bishops, Seleukeia was heard of no more.

As for the archaeology, very little is known about Seleukeia. Cursory investigations were conducted by a Princeton team in the 1930s but limited to a handful of houses and their mosaic pavements, namely, a Hellenistic peripteral temple, the so-called Market Gate, and finally the late-fifth-century-CE remarkable martyrion near the latter. Yet, it is plain that Seleukeia's city plan negotiated the steep slope through systems of terraces; strewn over an upper and lower city, its configuration is arguably reminiscent of that of Pergamon, albeit on a smaller scale. The city walls are of interest: while stretches of polygonal masonry survive on the eastern flank of the acropolis, the rest of the perimeter uses an isodomic technique that seemingly harks back to the early days of the Seleucid foundation. Measuring approximately five km of length, these walls were punctuated by potent rectangular and semicircular towers. Outside of them, along the road leading to Apamea, are a hippodrome (now covered by maquis and shrubs) and the necropolis at Mağaracık. Seleukeia's main attraction, however, is the so-called Titus Tüneli, the spectacular tunnel that diverted torrential waters and thus avoided the inundation and silting of the bay. Several inscriptions around the harbor, referring to Vespasian and Titus, leave no doubts about the agency involved in these works and underscore the size of this undertaking as without par.

The fortunes and the decline of Seleukeia in Pieria, it seems, cannot be divorced from those of its twin-sister city Antioch on the Orontes (Antakya, Turkey). Poised on the southwesternmost tip of the Amuq Valley, Antioch sits on a highly dynamic ecosystem. Three rivers demarcate this landscape: the Orontes, the Afrin, and the Kara Su. While the former follows its erratic course from south to north, the other two originally emptied their waters in the Amik Gölü, that is, the Lake of Antioch, now dry, after a vast 1960s reclamation plan.

Antakya is Antioch's modern reincarnation. Its features are typical of many modern Turkish towns: large boulevards, squares dedicated to the leaders of the modern Republic, and the chaotic allure of the bazaar. Antakya's gradual, almost tangible urban sprawling is ridding the city of old and ancient buildings by the day, and the modern cityscape bears no memory of what lies beneath.

Replete with great expectations, the 1930s excavations of Antioch were the first attempt to investigate archaeologically a city that had played a key role in the political landscape of Classical and Late Antiquity and had always attracted innumerable researchers thanks to the mediating powers of the textual sources. Financial cutbacks, strategy shortcomings, and ultimately pressures from the sponsoring institutions, however, greatly impaired the operations of the *Committee for the Excavation of Antioch and Its Vicinity*, thereby

hindering the effectiveness of this short-lived enterprise.

The mosaics, frescoes, and sculpture recovered – enthusiastically hailed as markers of Antioch's elites – have reduced the city's complexity to a mere constellation of luxurious suburbs with vistas on springs and idyllic landscapes. What is more, the city's topographical and social configurations remain by and large conjectural. Ironically, what was the Seleucid metropolis, the Roman provincial capital, the seat of the first Christian community, the virtual capital of the Near East in the fourth and fifth centuries CE, and the seat of the Count of the east – to name but a few titles – remains an uncanny, almost abstract entity. Simply put, Antioch and its vicinity are still unknown.

Today, only a handful of heavily battered monuments survive and conjure up the glorious past of the capital: the aqueduct of Trajan, the late antique fortifications, the stadium's piers, a pagan temple, and finally the church of St. Peter. The rich textual sources, however, compensate for the dearth of visible ruins. The texts of Josephus, Libanius, John Chrysostom, and Malalas plus a vast array of early Christian and Byzantine sources are key in tracing the building programs that shaped the capital city time and again. The inconsistencies, discrepancies, and vagaries that these texts present, however, hamper the realization of a more precise picture. For instance, the location of most sacred areas is speculative at best; while we know very little of the several sanctuaries that existed in Antioch and in its suburban extension Daphne, the picture for 31 churches reported by several authors is even more perplexing, as none of them can be situated in space.

Nevertheless, some general narratives of settlement and of building programs can be presented here. Antioch was apparently founded only a month after Seleukeia in Pieria. Honoring the memory of Seleukos' deceased father Antiochos, the city was built on a site where there had been favorable omens. In addition, the entire population of nearby Antigonia was forcibly relocated to Antioch; the former, founded by Antigonos in 306 BCE, may have ceased to exist shortly afterward.

The growth of Antioch began under Antiochos Soter and Antiochos III, when the island on the Orontes and the slopes of Mt. Silpius were incorporated within the urban grid, likely in response to the number of new settlers and veteran soldiers that the city continued to receive. Under Antiochos IV Epiphanes, however, some decisive changes occurred. The quarter of Epiphaneia was added to the city, thus modifying the overall urban layout that, however, would remain basically unchanged for the rest of antiquity. A new square was also added, which might correspond to the "Tetragonal" agora that was later to become the stage for the disorder of 69 CE. Furthermore, an aqueduct was added at this time, providing Antioch a continuous supply of fresh water. On a different note, Antiochos IV also commissioned the construction of the *Charonion* bust, an apotropaic monumental group defending the city from a plague's explosion. Though heavily weathered, it is still visible today and it is Hellenistic Antioch's only visible monument.

This Hellenistic city plan defined Antioch for ages to come; despite the many overhauls that the walls in particular underwent in the following centuries, the layout of the city remained unchanged. A solid grid-regulated space, punctuated as it were by two possible agoras and their correlated sanctuaries, followed the tradition of the great cities of Asia. The gradual addition of new urban quarters and the building of the royal headquarters on the island coalesced with the armature of the city, which at that point was structured around the main north to south thoroughfare. This road connected the various boroughs and also linked the city to south and northern Syria. Its modern reincarnation, Kurtuluş Caddesi, follows exactly the same trajectory.

More notably, however, this road was the locus for various manifestations of popular mobility: riots, acclamations, food distributions, and funeral parades, among others. Here, on this pivotal axis, Antioch's many historical layers converge. The grand military parade of Antiochos IV Epiphanes in 166 BCE, the mourning of the great general

Germanicus' body plausibly poisoned by Piso in the year 19 CE, and the solemn entrance of St. Symeon's coffin in 459 CE bring into focus the centrality of this axis within the constant reshaping of Antioch's urban and social fabrics. A unique commingling of emotions, political anxieties, and religious tensions unfolded along this boulevard, and demarcated some of Antioch's most momentous events.

Punctuated as it were by agoras and sanctuaries, the thoroughfare underwent major overhauls at the time of Herod the Great, when Syria and Antioch were firmly in Roman hands. Half a display of loyalty toward Augustus and half an act of *euergetism* toward a city that tallied a sizable Jewish community, newly designated as cardo, now embellished by porticoes and colonnades, it inspired the appearance of similar colonnaded streets in most cities of the Greek East.

This new addition to the urban matrix, however, was germane to the insertion of buildings and venues that advertised the spirit of the Augustan Peace. The theater of Caesar and a sequence of baths along the slope of Mt. Silpius contributed to redesigning the map of amenities in Antioch while conveying the essence of *Romanitas*. In more practical terms, however, Agrippa and Augustus promoted the wholesale implementation of new quarters at the end of the first century BCE, in a way that reminisced and perhaps deliberately replicated what the Seleucid kings had accomplished in the previous centuries.

Be that as it may, the city at the time of Tiberius may have been girded by new, larger, and more potent walls. Caution is in order on this point, however, as Tiberius of all the Julio-Claudian emperors went down in history for not having promoted major building programs in Rome, let alone in the provinces. Otherwise, as a token to Antioch's splendor, prestige, and remarkable pedigree, the city became the capital of Roman Syria enjoying a series of grants and tax immunities. The largesse with which these gifts were accorded must be questioned. Antioch had many assets; as early as the Julio-Claudian period, the city became instrumental in keeping the recalcitrant South Syria and Judea districts in check. Moreover, from there, the Euphrates region and the Parthian border could be reached with ease thanks to a network of roads that was promptly enhanced by Augustus in the first decades of his mandate. In practical terms, Antioch had to accommodate the governor and his substantial entourage, plus the entire military infrastructure of the east. It retained civic independence, but it came with a price.

In spite of vast building programs that included aqueducts, baths, stadiums, and other amenities, Antioch's armature remained substantially unvaried through the Islamic era. The Theodosian and Justinianic fortifications, though conspicuous, replicated earlier perimeters; new quarters and building programs allowed grandees from Agrippa to the bishop Ephraem in the early sixth century CE to declare their ambition onto the local cityscape. But by early Late Antiquity, Antiochene urbanites must have felt cramped in a city that was getting too crowded and too constructed. Urban chaos, noise, and confusion resonate in Theodoret of Cyrrhus' descriptions of the city. Antioch's built environment and its experience, however, constantly changed. The city never stayed a museum to its own self, far from it. The traditional agora which had marked the center of public space was replaced by the courtyards of great churches, *sermons in stone* as Peter Brown comments. Their wide open plazas became ideal venues for social and religious aggregation as well as proselytism; the daily routines of Paul of Samosata's parading through the agora in 260 CE while reading aloud to his clients from his official correspondence are well known. By contrast, the thoroughfare became the new heart of the city's economy after having been framed by porticoes and stoas as well as punctuated by shops. Earthquakes, fire, and floods had, however, their own share of responsibility in the reshaping of this community and in forcing continuous rebuilding and maintenance in Antioch.

Further upstream from Antioch lies the city of Apamea (Qalaat al-Moudiq, Syria), the best known among the *Tetrapolis*. According to Strabo, this city served as arsenal for the Seleucid kings as it accommodated thousands of mares and elephants as well as training facilities for the

soldiers. Outshined by its neighbor and Syrian capital Antioch in the Roman period, Apamea acquired visibility in the third century when it was base of the Legion II Parthica. It suffered greatly from Sapur's raids in 252 CE and from the sequence of earthquakes that shattered most urban foci in the sixth century. In the census of the year 6/7 CE, Apamea apparently tallied 117,000 citizens.

Thanks to the extensive Belgian excavations, Apamea is now well documented and attracts visitors by throngs. The site's well-preserved ruins, which in the main predate the earthquake of 115 CE, open vistas onto the planning solutions adopted by the Seleucid planners for the *Tetrapolis*.

Framed by a mountain called al-Saheliyeh and dominating the middle course of the Orontes and the Ghab Valley, Apamea was laid out on a conspicuous plateau accessible solely from its north side. A grid consisting of 105 × 53 m blocks created the basic armature, framed as it were by a 7-km-long system of fortifications that date to the third/second centuries BCE – the tumultuous days of the Syrian wars – but underwent numerous overhauls during the Roman and Byzantine periods. Well known are the third-century-CE repairs that employed a cache of funerary stones from nearby necropoleis. Overall, Apamea's built environment encompassed 250 ha of space, seized by domestic and public areas. The backbone is the colonnaded street, by far one of the best preserved in the Greek East. At 1850 m of length and almost 40 m of width and beautifully embellished by second-century-CE porticoes, it illustrates an architectural feature that was the signature of Greek cities in the east. At Apamea, this avenue linked the southern quarters to the Tycheion, the Agora, and the Great Baths, while also connecting suburbs to the city. Of importance is also the formerly prominent temple of Zeus Bêlos situated west of the colonnaded street, where emperors with the stature of Hadrian and Septimius Severus sought the response of the oracle, and the second-century-CE theater, one of the largest in Syria with its 140-m diameter. Also, it should be borne in mind that numerous houses have been excavated; by and large they date to the fifth and sixth centuries, and many showcase architectural and decorative solutions similar to the houses excavated in the 1930s near Antioch, Daphne, and Seleukeia in Pieria.

Finally, Laodikeia (Latakiyah, Syria) bore the lofty name of Seleukos' mother. Its population may have consisted in the main of Macedonian settlers, as attested by the 175 BCE decree that mentions the city's *peliganes*, a Macedonian term for city councilors. As with Apamea, Laodikeia was greatly affected by the political fluctuations of the Syrian wars, and it acquired independence as late as 83 BCE under Tigranes of Armenia. During the Roman era, it owed its reputation as hub for the shipment of its celebrated wine and to the famous incident that led to the downgrading of Antioch as kome (village) under Laodikeia's jurisdiction (so much for not siding with the just during the civil war of 193 CE). In the sixth century, Laodikeia was not exempt from suffering the blows of earthquakes, just as most of its Syrian counterparts.

Although obscured by the modern city, Laodikeia's urban configuration is fairly well known thanks to an early study by Jean Sauvaget. Built around its harbor, Laodikeia's design mirrors that adopted by the planners at Apamea, thus reinforcing the possibility that the same agencies were behind these foundations. A northern access, a colonnaded street, and *insulae* measuring 112 × 57 m are the features that legitimize this hypothesis. All the same, not much has survived among the temenoi and sanctuaries that allegedly punctuated Laodikeia's cityscape. A tetrapylon of the Severan period is the sole reminder of Laodikeia's heyday in the Roman era. Finally, it should be noted that Sauvaget's reconstruction of classical Laodikeia was long upheld to illustrate the transition from the classical colonnaded street to the enclosed and covered market, the suq of the Islamic period. As it stands, this model is based on a notion of cultural decline and degeneration from an age of order to one of political chaos; its

overall colonial posture is now called into question.

Aphrodisias, Archaeology of

Esen Ogus
Austin Peay State University, Clarksville, Tennessee, USA

Introduction

Aphrodisias is located on a plain south of the fertile Meander River valley, about 200 km southeast of Izmir in modern Turkey. The city was part of the region of Caria and the capital of the Roman province of Caria-Phrygia starting from the 250s CE. The city was well-known in antiquity for its cult of Aphrodite, sculpture production, and sculptors, who are known to have worked for domestic as well as Italian patrons.

Definition

Previous Excavations

The site was visited by several travelers in the eighteenth and nineteenth centuries such as William Sherard, Charles Texier, Sir Charles Fellows, Philippe Le Bas, and William Waddington, who mostly focused on recording the inscriptions of the site. Excavations were first conducted in 1904 by Paul Gaudin and later in 1937–1938 by Giulio Jacopi. Systematic excavations and research were begun in 1961 by Kenan T. Erim on behalf of New York University, until his death in 1990. After 1991, NYU excavations have continued under the directorship of R.R.R. Smith from Oxford University.

History of the Site

The site, with its buildings and monuments, is exceptionally well preserved, owing to its secluded location. The site's surviving monuments and material culture, the latter of which is predominantly in the form of marble sculpture, are mostly from the Roman and late antique periods and provide information on the history of the site

from the Republican period to the fifth century CE. Some 2000 inscriptions preserved on the site, on the other hand, illuminate the social history of the site and life in Roman Asia Minor in general.

According to Greek tradition and a legend recorded by Stephanus of Byzantium, the city was founded by Ninos, who was the mythical founder of the Assyro-Babylonian Empire and the husband of Semiramis. There are substantial remains from the prehistoric and Bronze Age periods of the city, which were excavated from the two prehistoric mounds, the Theater Hill (Acropolis) and the Pekmez mound (Joukowsky 1986). There are fewer remains excavated so far from the archaic and classical periods. From the second century BCE onward, the city grew around the sanctuary of Aphrodite, and witnessed major urban development in the first century BCE onward. By this period, as evident from coins, Aphrodisias was in a "sympolity," or close political or religious union, with Plarasa, a nearby city, which may have been the present-day village of Bingeç (Reynolds 1982: Doc. 2, 11–16).

One of the major sources for the history of the site, the north parodos wall of the theater, the so-called archive wall, provides information about the early urban development of the site. In 39 BCE, after the city's loyalty to Rome against Labienus, who plundered both the sanctuary and private property, the city was granted freedom, nontaxable status, and increased asylum rights in the sanctuary of Aphrodite. The granting of these privileges was without doubt a major influence of Octavian/Augustus.

In the imperial period, the city kept its "free" status until 250s CE when it became the capital of the province of Phrygia and Caria. The first and second century CE saw major construction of marble monuments and urban development at the site (Ratté 2000). This construction stopped in the second half of the third century, but the city kept its vital culture under the influence of Roman governors. The rise of Christianity eventually put an end to the cult of Aphrodite. In the fourth century CE, the city had a bishop. In the fifth century, however, it was still home to a leading school of pagan Neoplatonic philosophy. The site gradually depopulated and turned into a village starting from the seventh century and became home to a Turkish population beginning in the fourteenth century.

Key Issues/Current Debates

Major Monuments and Urbanism

The North and South Agora

There are two agoras at Aphrodisias, but the older and true civic center is the North Agora, which lies in the area immediately to the south of the Bouleuterion and to the west of the Hadrianic Baths (Smith and Ratté 1998). The space was surrounded by colonnades on all four sides. Excavations have shown that only the northern and southern colonnades had a double row of colonnades, whereas the eastern and western ones each had a single row (Smith and Ratté 1997). The northern colonnade of the North Agora was dedicated in the first century BCE by C. Julius Zoilos, an Aphrodisian, who was also the freedman of Octavian/Augustus. The southern colonnade of the Agora is adjacent to the Portico of Tiberius, a colonnade that carried a mask and garland frieze.

The South Agora is a rectangular porticoed enclosure to the south of the North Agora and is bordered on the north side by the Portico of Tiberius, on the south by a portico and the Theater Hill, and on the west by the Hadrianic Baths. The South Agora seems to have been laid out as a consequence of second century CE urban development, and an earlier possible formulation of the area is ambiguous. In the second century, a columnar two-storey gate, known as the "Agora Gate" or the "East Gate" was added to the east end. Around the same time, an extraordinarily large (c. 175 × 25 m) rectangular pool with rounded ends was built in the center of the Agora (Wilson 2016: 109). As evident from two reused inscribed blocks, the space between the Agora Gate and the pool, as well as the unpaved area all around the pool – between the porticoes and the marble pavement surrounding the pool – was likely to be a palm grove (Reynolds et al. 2007: Doc. 12.204 = Calder and Cormack 1962: Doc. 448; Reynolds et al. 2007: Doc. 4.202.i = Roueché 2004:

Doc. 38; Wilson 2016: 129). The South Agora, therefore, would have been a shady park, rather than a traditional agora, surrounded by porticoes and planted with palms, which provided leisure space to Aphrodisians.

The South Agora was heavily renovated and repaired in Late Antiquity. The west portico was rebuilt in the fifth or sixth century CE (Roueché 2004: Doc. 83), and the south portico was renovated in Late Antiquity (Reynolds et al. 2007: Doc. 4.19 = Roueché 2004: Doc. 66; Wilson 2016: 107). Ancient cracks and repairs on the columns and clamps suggest that the north portico was also repaired later. A major renovation activity took place to rebuild and restore the Agora Gate, undertaken by the governors Dulcitius and Ampelius in the late fifth or early sixth century CE (Roueché 2004: Doc. 38–40 = Reynolds et al. 2007: Doc. 4.202.i–iii). This is evident from the three inscription blocks built on the Agora Gate to honor those responsible for the extensive renovation. Around the same time, but probably slightly later, a large water basin fed by pipes was added in front (west) of the gate. The basin is too deep to be a collecting basin; rather it probably served as a supply tank for the pool (Wilson 2016: 130–134).

The Temple of Aphrodite

The first marble temple of Aphrodite was a prostyle building of the late first century BCE, which was turned into a pseudodipteros in the first century CE (Smith and Ratté 1995). Two features were added to the sanctuary in the second century: the temenos surrounding it and the monumental gateway of the temenos courtyard in the east ("Tetrapylon"). In Late Antiquity, probably around 500 CE, the temple was converted into a Christian church and remained in use until the Middle Byzantine period (Smith and Ratté 1995: 46). Major restructuring was necessary for the conversion (Cormack 1990: 75–88; Hebert 2000: 13–14). The 8 × 13 m cella was dismantled to build the walls of the church, and the columns on the (short) east and west sides were repositioned to align with the long sides on the north and south. The main entrance was moved to the west, and an apse was added to the east. Narthexes and an atrium were built on the west, and the north and south sides of the temenos were modified: while the south portico remained standing, the colonnade of the north portico was stripped away.

Even though with the conversion of the temple, the Tetrapylon, and the courtyard it gave access to lost their function, the Tetrapylon was left standing by Christian builders probably because it was an iconic monument that represented the city's identity and the past. It was even re-erected in the late fourth or early fifth century after its probable destruction in an earthquake, datable by two coins presumably used as shims, found in the 1980s under one of the column pedestals (Paul 1996: 208).

The Sebasteion

The Sebasteion, discovered in 1979, is a large temple and sanctuary complex dedicated to Aphrodite and the Julio-Claudian emperors. Construction of the complex was undertaken by two local families and began in the reign of the emperor Tiberius, c. 20 CE, having brought to an end early in the reign of Nero, c. 60 CE. The structure was a long and narrow street with a three-storey building on the north and south sides, a propylon on the west end that opens onto the main north-south avenue of the city, and a temple dedicated to Aphrodite and Roman emperors on the opposite east end of the complex. The building complex presents an unusual combination of well-preserved architecture, relief sculpture, and inscriptions. There are about 80 surviving panels of relief sculpture from the facades of the south and north buildings, which are either mythological or allegorical/imperial in content (Smith 1987). The mythological reliefs are unusual in that they provide us with the surviving visual vocabulary of ancient mythology in the Roman period. The allegorical/imperial reliefs, on the other hand, present a glimpse of the reception of Roman emperors in this eastern city. Excavations have shown that almost nothing beyond the façade remains of the temple, which was replaced in antiquity by domestic structures. The propylon, however, continued to be used until it entirely lost its function in Late Antiquity. It was an unusual two-story columnar structure in the form of a double-sided screen – rather than a columnar

facade with a back wall. The columnar screen displayed several statues of the imperial family on their bases at least on its first storey.

The Theater

The Theater, a semicircular structure leaning over the hill of the Bronze Age occupation, was built in two major stages. The earliest phase was the construction of the stage building, dedicated in 28 BCE by C. Julius Zoilos, the same freedman who dedicated the north colonnade of the Agora. The second phase was the building of the auditorium out of marble, which was a Julio-Claudian undertaking and was perhaps still under construction in the Flavian period. The seats above the diazoma are lost today. Excavations in the 1960s and 1970s have unearthed the auditorium, the blocks of the stage building, which was restored on the first storey, and the so-called archive wall to the north of the *logeion* that records the communications between the city and Rome. Recent studies have reconstructed the stage facade (De Chaisemartin and Theodorescu 2017). The fourth-century CE colonnaded square to the west of the Theater, called the "tetrastoon," was also cleared of blocks. Recent efforts have focused on studying the architecture of the tetrastoon as a whole, together with its inscriptions and statues and its contribution to the late antique urban plan of the site.

The Hadrianic Baths

The baths were built in the early second century CE and dedicated to Emperor Hadrian. The building, located at the west end of the South Agora, consists of three parts: a series of barrel-vaulted rooms, a forecourt with marble architecture in the east, and a late antique court (the "tetrastyle" court) with a central pool in the north. Excavations in 1904–1905 and then in the 1960 revealed the walls of the main bathing block; its floors, including the well-preserved hypocaust system; the marble court; and the tetrastyle court and its sculpture. Recent studies have focused on the Baths once again, with the aim of conserving the monument, explaining its architecture and historical phases, and opening it to the visitors (McDavid 2016; Öztürk 2016).

The Bouleuterion

The building was the seat of the *boulē* and is a small semicircular auditorium on the north edge of the Agora, with a shallow stage building. The marble seating of the lower cavea survives intact, but the section above the diazoma has collapsed. The stage building was a two-storey structure with niches decorated with honorific statues and statues of deities. One of the major questions surrounding the structure is its exact chronology. The main structure dates to the second century CE with distinct Antonine and Severan phases. It remains elusive, however, whether there was an earlier first-century structure on the site (Smith and Ratté 1996). The Bouleuterion was used through Late Antiquity. Several changes to the architecture were made to enlarge the orchestra for performances in the fifth century CE, when the cornice molding of the stage front (or *pulpitum*) was incised with an inscription identifying the patron (whose name is missing) of the *palaestra*. The word *palaestra*, originally meaning wrestling place, could have been used metaphorically to refer to various competitions taking place in the building (Roueché 2004: 79).

The Civil Basilica

The Civil Basilica – as opposed to a Christian basilica – is a long hall extending southward from the South Agora (Stinson 2008; Stinson 2016). Excavations since 1962 have documented the architecture and relief decoration of the building. The building, with a central hall flanked by two side aisles and a hall in the south opened to the main nave by arches, combined a Roman basilica with a Hellenistic stoa and meeting hall. The two-storied structure had an Ionic order on the lower storey and a Corinthian order on the upper one, with engaged half-columns and balustrade-like reliefs at the bottom of the columns. Built in the Flavian period, the building probably had a multipurpose public function, including banking, money changing, and engaging in scribal activities and legal contracts. The building also served as a site to display important relief sculpture and inscriptions. There were reliefs and niches for statuary along the side walls of the long hall.

The South Hall may also have served as an honorific hall for Flavian emperors and other dignitaries. In the fourth century CE, the north façade of the building became a surface to display Diocletian's Price Edict. Recent excavations have revealed the pillar capitals from the South Hall that were decorated with bull and lion protomes (Stinson 2016).

The Stadium

The 270-m-long building, entirely built of marble, is the best preserved example of its type. It has an unusual double-ended design with the auditorium running in semicircle on both ends. The structure has a seating capacity of 30,000 people, which is above the entire population of the city itself, showing that it was designed to host games for guests. The east end of the structure was converted into a small amphitheater in Late Antiquity (Welch 1998).

Domestic Architecture

Three major house complexes were excavated beginning in the 1980s and shed light on a portion of the domestic life of the city in Late Antiquity. One of the most significant domestic complexes on the site is the "Bishop's Palace," which was named so based on its proximity to the cathedral, but is now known as the "Triconch House" after its most prominent architectural feature (Berenfeld 2009). The house conveys the architecture and layout of a late antique house in the city and its relationship with the wider urban environment.

A second major house complex is the "Atrium House," which is adjacent to the back wall of the northern portico of the Sebasteion and consists of two complexes: an atrium complex to the north and an apsidal building to the south. The archaeology of the building and its peculiar sculpture, which includes a series of late Roman philosopher portraits, has been well examined (Lockey 2016).

A third housing complex of late antique date is the "North Temenos House," which is adjacent to the Temple of Aphrodite (Smith and Ratté 1998). A building with a large apsidal hall, the structure provided a mosaic floor and a series of late antique pilaster capitals with bucolic scenes.

Regional Survey

An archaeological survey of the surrounding areas was conducted between 2005 and 2009. The survey has documented several Hellenistic-Roman or pre-Hellenistic settlements, fortifications, Byzantine churches, inscriptions, aqueducts, marble quarries, tumuli, tombs, and sarcophagi, which were catalogued and published in a volume (Ratté and De Staebler 2012).

Sculpture Studies

Marble workshops and sculptors from the city provided for both domestic and Italian patrons. For example, some sculptures from Hadrian's Villa at Tivoli and the Esquiline statues in Rome are signed by Aphrodisian sculptors. Due to the massive amount of Roman marble sculpture, both free-standing and in relief, sculpture studies have been one of the main focal points of the current excavation project. Several studies have dealt with Roman and late Roman portrait sculpture, relief sculpture from the Zoilos monument (Smith 1993), Sebasteion (Smith 2013) and the Civil Basilica (Yıldırım 2008), the Aphrodite of Aphrodisias (Brody 2007), mythological reliefs from the Agora Gate (De Bellefonds 2009), sarcophagi (Öğüş 2014; Ogus 2018), and other pieces of sculpture material.

Epigraphy Studies

The epigraphic documents from the city, which survive in unusual numbers and provide tremendous information on the history of the site, have been studied since the eighteenth century by various scholars including Sir Charles Fellows, William Waddington, William Paton, and Louis Robert. NYU's systematic excavations carried out in the years 1961–1995 had Joyce Reynolds and Charlotte Roueché as epigraphers, who created the invaluable online database known as "Inscriptions of Aphrodisias" (Roueché 2004; Reynolds et al. 2007). From 1995 onward, the epigraphy of the site has been studied and published by Angelos Chaniotis (2004, 2016).

Future Directions

Current research and planned future research at Aphrodisias can be reviewed under two separate headings: (1) the excavation and conservation of monuments and (2) the publication of major monuments and sculpture. In terms of the excavation of the site, there are two main focus areas: the north-south avenue of the city and the South Agora pool. The main north-south avenue connects the monumental gateway of the Temple of Aphrodite to the propylon of the Sebasteion and the theater. This avenue, renovated in Late Antiquity, has been excavated and conserved along its length since 2008 to answer questions regarding the Roman and late antique urban layout of the city and to enhance the visitor's experience of the site (Öğüş 2016; Sokolicek 2016; Yıldırım 2016).

Other recent excavation efforts focus on the South Agora pool (Wilson et al. 2016). The east and west ends of the pool were partially dug out in the excavations in 1988–1989, under the directorship of late Kenan T. Erim. A new initiative that began in 2012 aims to expose the entire pool area and conserve the pool and the surrounding porticoes in its ancient appearance as an urban park.

The conservation and restoration of the existing monuments have been a major part of seasonal activity at Aphrodisias, and one of the most significant of these efforts is the anastylosis of the east corner of the south building of the Sebasteion. For this project, plaster casts of several reliefs were made and installed on the facade of the structure, whose architectural blocks have mostly survived. Following the completion of this project, another anastylosis project was undertaken, that of the propylon of the Sebasteion. The first storey of the propylon, including columns and architrave blocks, was re-erected mainly using original architectural pieces. When original pieces do not survive, plaster casts of architectural blocks were made. This project provided several clues about the overall appearance of the propylon and its spatial relationship with the avenue that ran in the front, as well as the original setup of the statues on the propylon.

Another major conservation project has focused on the Hadrianic Baths and includes wall capping and re-bedding of the tile floors. The aim of the project is to protect the walls and floors of the rooms of the Baths from further damage and secure them well enough to open the complex to visitors.

Several site monographs have been published. The first two by the excavation director R.R.R. Smith deal with the funerary monument of C. Julius Zoilos (Smith 1993) and the Roman portrait statuary from the site (Smith et al. 2006). The third volume is on the Aphrodite of Aphrodisias (Brody 2007), and the fourth monograph is about the mythological reliefs from the Agora Gate (de Bellefonds 2009). More recent site monographs have dealt with the Aphrodisias regional survey (Ratté and De Staebler 2012), Sebasteion reliefs (Smith 2013), Civil Basilica (Stinson 2016), the theater stage building (De Chaisemartin and Theodorescu 2017). A forthcoming volume is on the Sculptor's Workshop (van Voorhis forthcoming), and another one is on the columnar sarcophagi from the site, exploring the relationship of social history with local burial culture (Ogus 2018).

Applied Archaeology (Including Activist Archaeology)

M. Jay Stottman
Kentucky Archaeological Survey, University of Kentucky, Lexington, KY, USA

Introduction

All archaeology is inherently applied in some way. As the study of the material remains of past cultures, it has been primarily applied as a means to learn about the past. It, however, has also been applied to a wide variety of uses that extend beyond research of the past. Despite this fact, applied archaeology is a label that has, throughout its history, seen sporadic use among archaeologists and has had a history of ambiguous meanings. Consequently, the term applied archaeology has been used to refer to many types of archaeology often interchangeably. More recently it has been used to refer to archaeology that takes an activist perspective and has concern for contemporary communities. In this entry, I will examine the various iterations of applied archaeology and the history of its development.

Definition

Defining applied archaeology seems like a rather simple thing to do, one that can be assumed to have been done many times; however there are few archaeologists that have offered definitions. Perhaps it is apparent that applied archaeology is a self-explanatory term that means any application of archaeological research and methods. It, however, has most often been referred to as applications of archaeology outside of traditional academic research, meaning that applied archaeology has a more practical and public purpose (Gunn 1978). This definition is indeed very broad encompassing most of the archaeology conducted around the world. Downum and Price (1999) made the most extensive effort to examine this definition and applied archaeology's potential. I have distilled more recent concepts of applied archaeology into this simplified definition: the application of archaeological research, methods, and theory to assist the public in addressing societal problems and issues. This definition by no means is the result of some consensuses among archaeologists, but it is a culmination of the evolution of applied work in archaeology that is presented below.

Historical Background

The Beginnings of Applied Archaeology

Since the initial beginnings of a formalized archaeological practice in the nineteenth century, archaeologists have occasionally stepped beyond traditional research into the politics, culture, and motivations of their societal contexts. Unfortunately most of these forays into contemporary society were often misguided, having dire consequences for contemporary peoples. Evolutionary approaches to archaeology during the late nineteenth century helped foster racist justifications for the rampant colonialism of the time. The use of unilineal concepts of cultural evolution helped to establish perceptions that less complex cultures were inferior and less evolved, which were used to justify the colonization of Africa, displacement of aborigines in Australia, and removal of Native Americans in North America (Trigger 1989).

As the direct historical or cultural-historical approach began to replace evolutionary thought

at the beginning of the twentieth century, archaeologists became more focused on understanding the history and development of contemporary cultures, tracing their origins back to prehistory. This approach emphasized the prehistory of specific historic and contemporary cultures in specific areas, which were exploited by nationalist and racist agendas of the time (Trigger 1989). Politically astute archaeologists knew the danger of an intersection of cultural history and contemporary politics, leading to a rejection of racist explanations for cultural variation (Dawdy 2009; Trigger 1989).

Some archaeologists, such as Gustaf Kossinna, were motivated by politics in their archaeological work. Kossinna employed archaeology to search for the prehistoric German homeland, which served to feed the national patriotism and imperialism sweeping through Germany just before World War I (Trigger 1989). Although Kossinna died in 1931, his propagandistic research caught the attention of the Nazis who used it to build their racist national identity from the ashes of the war and as the backbone of their ambition to conquer Europe and eradicate inferior cultures. It can be argued that archaeology used in this way aided the waging of the most destructive war in world history and helped justify the Holocaust (Dawdy 2009).

Although it was not called applied archaeology, this example demonstrates early uses of archaeology beyond traditional research, spilling out into the politics of contemporary society with disastrous consequences. With such an inauspicious beginning, it is no wonder that an applied archaeology failed to fully develop, and practical applications of archaeology would be limited in the years immediately after World War II.

CRM as Applied Archaeology

Not all nationalistic archaeology was used for nefarious purposes. The focus on national identity in many countries led to the development of historic preservation and heritage management of which archaeology was an integral part (Neumann et al. 2010). For example, buildings and sites important to the history of the United States became protected through several laws starting in the early 1900s. For many countries national archaeology became intertwined with the government for the purpose of protecting history and heritage for the public good. It is within this context that the term applied archaeology is first used to describe applications of archaeology outside of academia. Perhaps fearful of its colonial and nationalistic past, academia seemed content to avoid such an applied archaeology, setting up an academic and applied dichotomy that would persist for decades. The hesitancy of academia to embrace applied archaeology gave rise to cultural heritage management, also known as archaeological resource management (ARM) or in North America cultural resource management (CRM), and its dominance of the term applied archaeology (Gunn 1978). I will use CRM here to refer to this specific type of applied archaeology.

The management of historic, cultural, heritage, or archaeological resources, such as historic sites, buildings, monuments, landscapes, archaeological sites, etc., was born out of national and salvage archaeology programs. Because of rampant development and the desire for national identity after World War II, the management of these resources has been focused on the protection and interpretation of heritage sites. Most of this management is conducted under the auspices and authority of governments in the public's interest (Neumann et al. 2010). Archaeology became an integral part of the CRM process, which occurred around the time that a major paradigm shift in archaeological theory was taking place. The processual theoretical movement in archaeology was partly focused on understanding broader cultural processes, which was conducive to CRM's archaeological focus of inventorying resources and collecting data. Thus, the CRM movement spurred the development of an archaeology industry known as contract or private sector archaeology, which has grown to employ most archaeologists working around the world today.

As such, it has come to epitomize and is synonymous with applied archaeology, so much so that the term became rarely used.

Applied Archaeology Beyond CRM

Archaeologists have used the methods of archaeology to address contemporary issues outside of the CRM context before, for example, the William Rathje's Garbage Project in the 1970s and 1980s. Although this and other similar projects were largely motivated by testing archaeological methods within positivistic theoretical frameworks, this research produced valuable information regarding the nature of contemporary garbage disposal practices that have been applied to better understanding problem of dwindling landfill space in more recent times (Little and Zimmerman 2010).

The reactions to processual theoretical perspectives in the late 1970s and early 1980s spurred the post-processual movement to inject more contextual and humanistic thinking into archaeological theory. In particular Marxist and critical theoretical approaches brought self-reflexivity and a sense of political engagement in archaeology that would help revive the use of the term applied archaeology and begin to expand it beyond the shadow of CRM. During this period, archaeologists were becoming more interested in applying archaeology outside of CRM, and its public interest mandates to more practical benefits for the public at large (Gunn 1978). Thus, archaeologists were becoming more aware of the social and political environments in which their research was conducted and presented. Some saw archaeological research as having the ability to empower and change present-day people with knowledge of the past. This type of thinking was more like what was happening in the burgeoning field of applied anthropology than it was in CRM (Downum and Price 1999; Gunn 1978). It was a logical next step that archaeologists began to look toward applied anthropology in order to reconceptualize applied archaeology.

Archaeology as Applied Anthropology

Although applied anthropology had a similar beginning to applied archaeology, it developed differently and thus had been well established by the time that CRM was developed. Applied anthropology has had a number of definitions throughout its history; however a definition which provides a basic concept of the field is "the application of anthropological knowledge, methodology, and theoretical approaches to address societal problems and issues" (Kedia and van Willigen 2005). Within this concept anthropology is applied in a great number and diversity of domains. Cultural resource management is considered to be one of many domains of application that anthropologists, through archaeology, work (Kedia and van Willigen 2005). Given the above definition of applied anthropology, it is clear that CRM is certainly an application of archaeology and anthropology; however it is also clear that this application of archaeology is limited and that it has the potential to be applied within many of the other domains in which applied anthropologists work. Anthropologists have long worked in agriculture, economic development, education, environment, health, politics, media, the military, and human rights just to name a few (Kedia and van Willigen 2005). Nearly all of these domains have some relationship or connection with the public. Similarly an expanded applied archaeology also had to be engaged with the public in many ways.

Applied Archaeology and the Public

All concepts of applied archaeology are inherently public, meaning that applied archaeology has some connection or relationship to the general public. In part, it is this relationship with the public that allowed CRM to not only become synonymous with applied archaeology but also public archaeology. This concept of CRM is predicated on doing archaeology for the public or in the public's interest (Little and Zimmerman 2010). Thus, CRM was an application of archaeology to preserve and protect cultural resources in

the public interest through government regulation. This form of public archaeology was more public trust than public interest, as it placed the archaeologist in a position of power as a gatekeeper to place cultural resources in trust for the public, often out view of the public. However, the very government institutions that created the cultural resource power structure later forced CRM to interface with the public in a different way as pressure mounted to consider descendant groups as stakeholders in decisions about cultural resources and to justify the expenditures made in the name of culture resource management. CRM archaeologists found themselves on the front line of interaction with the public and as the public face of archaeology.

Although there have been many forms of public outreach and interaction outside of CRM throughout the history of archaeology, public archaeology did not take significant steps to expand beyond CRM until the 1980s. Through post-processual concerns for self-reflexivity and the desire to apply archaeology to contemporary issues, public archaeology programs, such as those conducted in Annapolis, Maryland sought to inform the public with knowledge produced by archaeological research and show them how that information was produced. It was the intention of the archaeologists to use the past discovered through archaeology to enlighten people in the present about their condition within capitalistic societies and act to change it (Potter 1994).
